Patiala – 147 004

## Certificate

I hereby certify that the work which is being presented in the thesis entitled “**Enhancement of Critical loading for Electric power Distribution Systems**” in partial fulfillment of the requirement for the award of degree of “Doctor of Philosophy” submitted in Department of Electrical and Instrumentation Engineering of Thapar University, Patiala, is an authentic record of my own work carried out under the supervision of Dr. Smarajit Ghosh and refers other research work which are duly listed in the reference section.

The matter presented in this thesis has not been submitted for the award of any other degree of this or any other university.

  
(Kultar Deep Singh)

Regn. No. 900804001

This is to certify that the above statement made by the candidate is correct and true to the best of my knowledge.

  
(Dr. Smarajit Ghosh)

Professor

Department of Electrical and Instrumentation Engineering

Thapar University, Patiala.

Punjab, INDIA-147004

# Acknowledgements

I would like to express my sincere appreciation to my supervisor, **Prof. Smarajit Ghosh**, for his support and encouragement throughout my research work. His experience, strength, tenderness and willfulness, has taught me the lessons of life, which are of immense help to me to take the decisions in my every endeavour.

I am thankful to my doctoral committee members, **Dr. S. S. Bhatia**, Prof. and head of School of Mathematics and Computer Applications (SMCA), Thapar University, Patiala, and **Dr. Mandeep Singh**, Associate Professor, Department of Electrical and Instrumentation Engineering for their constructive comments and regularly ensuring the progress of my research work. I am thankful to Dean of Research and Sponsored Projects **Dr. P. K. Bajpai** for his affection and blessing during this thesis work. I am thankful to all the faculty members and staff members of Department of Electrical and Instrumentation Engineering for their cordial behavior.

I am also thankful to **Mr. S. P. Yadav** for his kind support from starting of thesis work to the completion of the work

I offer deepest gratitude to my family members for their love and moral support.

(Kultar Deep Singh)

*Dedicated to my grand mother*

## *ABSTRACT*

In this thesis it has been tried to explore the possibilities of enhancement of critical loading of radial electrical power distribution networks. It has been found that the critical loading can be enhanced by optimal conductor size selection, optimal capacitor placement, and network reconfiguration. To apply these corrective steps on the distribution networks an efficient load-flow solution method is required so that the actual condition related to node voltage and its angle, branch current, real power loss, reactive power loss, branch losses etc. of the network can be studied and analyzed. A new efficient method is proposed for load-flow solution of radial distribution networks. Simple transcendental equations are used to relate the sending-end voltage, receiving-end voltage and voltage drops in each branch of the distribution system. The effect of charging capacitance of the line has been incorporated in load-flow solution. A computer algorithm is developed in such a way that there is no need to adopt any sequential node numbering scheme for the solution of the networks. The angle of the receiving-end voltage is also computed along with the magnitude of the voltage. It is an iterative method. The flat voltage (1p.u.) start from substation to every end-node is considered. The voltage magnitude and angle are updated after each successive iteration and the voltage drops are then computed by using the new obtained values of voltage magnitude and angle. The comparison of speed and memory requirement by the proposed method with the other methods has been verified to show its efficiency.

To investigate the present state of loading and loadability limit, a line loadability index is derived. The change in resistance with the change in operating temperature of the

branch conductors is incorporated in the computation of voltage stability index and line loadability index. The voltage stability index computes the voltage stability limit of the radial distribution network in the fault conditions or at the time of load contingency, it identifies the most sensitive node of the distribution network and gives information about time within which the voltage collapse will occur for above said conditions. The line loadability index is based on the maximum permissible steady state operating temperature of the line conductors. The loadability limit of the distribution network is supposed to be within the maximum permissible operating temperature of the conductor. Line loadability index gives the loadability limit of the network in normal steady state conditions and identifies the most sensitive branch of the network. The values of voltage stability limit and line loadability limit are not unique for a distribution networks, the values might be different for the same network in different ambient conditions. So a very practical aspect is incorporated in the proposed work. The importance of the proposed voltage stability index is discussed in context of over current protection. The proposed voltage stability index and line loadability index can be used for voltage stability study and the loadability margin, optimal conductor size selection, capacitor placement studies, reconfiguration of distribution networks, over current protection system design etc. at planning stage as well as in operation of the electrical power distribution system.

The current carrying capacity, critical loading and voltage stability of distribution networks depend upon the conductor sizes applied to each branch of distribution network. Hence the optimal conductor size selection is utmost necessary. A method for optimal conductor size selection is proposed in this work. The conductor sizes are first selected according to the current carrying capacity of the available conductor sizes, then upgraded

through economical optimization. After selecting the economical conductor sizes, the constraints regarding the maximum limit of branch operating temperature and the minimum voltage level at the end nodes are applied and the up gradation of the candidate branches is carried out. While selection of the optimal conductor size for each branch of the distribution network, the effect of change of resistance with the change of temperature is incorporated. This incorporation leads to exact computation of real power losses of the network, actual thermal behavior of branch conductor in practical situations and optimal conductor size selection according to weather conditions of the region. The results are compared with the existing methods to establish the goodness of the proposed approach.

The critical loading and voltage stability are related to the system's voltage profile. The voltage profile of distribution network can be improved by reducing the reactive component of power by optimal capacitor placement. Capacitor placement problem is dealt with different way in this work. Capacitors are placed at the nodes where the reactive power demand is occurred. The capacitor sizes are selected on the basis of economical analysis. The shunt capacitor is more economical when it is placed as near as possible to the load causing low power factor. In the proposed, method it has been computed at first the summation of real power losses from substation to each node. The node having highest value of losses is taken as the candidate node and the smallest capacitor size is placed at that node and the objective function is again computed. The level of reactive power compensation is increased till it generates the economical benefits. All the nodes are tried in this manner. The results are compared with the existing method and the proposed method is found better in each aspect.

The enhancement of critical loading and voltage stability can be achieved from the existing network through network reconfiguration. The reconfiguration of distribution network is dealt with different point of view in this work. The possibilities of network reconfiguration are identified from the chronological load curves of the laterals of distribution network. The load can be shifted from one lateral of distribution network to the other lateral due to the seasonal change in load demand. The enhancement in critical loading and enhancement in voltage stability after network reconfiguration are shown with the help of a test system.

## *TABLE OF CONTENTS*

<b>Chapter Number</b>	<b>Title</b>	<b>Page Number</b>
<b>CHAPTER 1</b>	<b>INTRODUCTION</b>	
1.1	Introduction	1
1.2	Critical Loading	3
1.3	Objectives of research	4
1.4	Scope of research	5
1.5	Organization of research	6
<b>CHAPTER 2</b>	<b>LITERATURE SURVEY</b>	
2.1	Literature survey of electric power distribution networks	10
2.2	Survey on load-flow of electric power distribution networks	10
2.3	Survey on line loadability index and voltage stability index of electric power distribution networks	12
2.4	Survey on optimal conductor size selection for electric power distribution networks	14
2.5	Survey on optimal capacitor placement for electric power distribution networks	16
2.6	Survey on network reconfiguration for electric power distribution networks	18
<b>CHAPTER 3</b>	<b>LOAD-FLOW SOLUTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS</b>	

3.1	Introduction	23
3.2	Assumptions	24
3.3	Formulation of load-flow method	24
3.3.1	Derivation of expression of magnitude of voltage and angle of the voltage at each node	24
3.3.2	Formulation of power losses	26
3.4	Load modelling	27
3.5	Solution methodology	28
3.5.1	Formation of lateral arrays	29
3.5.2	Load-flow solution	31
3.6	Convergence criteria	33
3.7	Application of the proposed method	33
3.8	Conclusion	48

**CHAPTER 4 LINE LOADABILITY INDEX AND VOLTAGE STABILITY INDEX FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS**

4.1	Introduction	49
4.2	Formulation of Voltage stability index and Line Loadability index	52
4.2.1	Voltage stability index ( <i>VSI</i> )	52

4.2.2	Line Loadability index ( <i>LLI</i> )	54
4.3	Incorporation of change in resistance with the change in temperature	54
4.4	Computation of voltage stability index and line loadability index	57
4.5	Examples	58
4.5.1	<i>VSI</i> at base load	59
4.5.2	Voltage stability limit	61
4.5.3	Comparison of results with existing methods	64
4.6	The conditions practically possible when voltage collapse can occur in radial distribution networks	65
4.6.1	Voltage stability limit for constant power load	73
4.6.2	Voltage stability limit for practical type load	74
4.7	Voltage stability limit and Line loadability limit for different ambient conditions	77
4.8	Line loadability limit	79
4.9	Conclusion	83

**CHAPTER 5 OPTIMAL CONDUCTOR SIZE SELECTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS**

5.1	Introduction	84
5.2	Problem formulation	86

5.3	Objective Function	86
5.4	Constraints	87
5.5	Procedural steps for optimal conductor size selection	89
5.6	Values of various parameters used	90
5.7	Examples	92
5.8	Effect of environmental conditions on Choice of conductor	112
5.9	Effect of load modelling on choice of conductor	113
5.10	Enhancement of Line Loadability and voltage stability of radial distribution network by optimal conductor size selection	115
5.11	Conclusion	122

**CHAPTER 6 OPTIMAL CAPACITOR SIZE SELECTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS**

6.1	Introduction	123
6.2	Problem formulation	124
6.3	Economical selection of capacitor sizes	125
6.4	Constraints	125
6.5	Fixed and Switched capacitors	125
6.6	Algorithm for optimal sizing and location of shunt capacitors for radial power distribution networks	126
6.7	Examples	127

6.7.1	Example 6.1	127
6.7.2	Example 2	133
6.8	Enhancement of line loadability and voltage stability after capacitor placement	137
6.9	Conclusion	139
<b>CHAPTER 7 NETWORK RECONFIGURATION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS</b>		
7.1	Introduction	141
7.2	Problem formulation	142
7.3	Constraints	142
7.4	Procedural Steps for network reconfiguration	143
7.5	Example	143
7.6	Conclusion	164
<b>CHAPTER 8 MAIN CONCLUSION AND FUTURE SCOPE OF WORK</b>		
8.1	Main conclusion	165
8.2	Future scope of research	168

## *LIST OF SYMBOLS*

N: Total number of nodes.

SN, RN: Sending-end node and receiving-end node.

k: Node Number :1, 2, 3,..... N.

jj: Branch number :1, 2, 3,..... N-1.

$V_k$ : Sending-end voltage.

$V_{k+1}$ : Receiving-end node's voltage.

$\delta_k$ : Sending-end node's voltage angle.

$\delta_{k+1}$ : Angle of Receiving-end node's voltage.

$I_{jj}$  : Branch current.

$Z_{jj}$  :  $R_{jj} + jX_{jj}$ , Branch impedance.

$y_m^c$  : Admittance of the charging capacitance.

$P_m$  and  $Q_m$  : Real load and reactive power load respectively connected to the node (m).

$L_1, L_2, L_3, \dots$  are the arrays to store node numbers of feeder and laterals the distribution network.

JN and LN are two dimensional arrays.

$q_{jic}$  : Convicted heat loss rate per unit length W/m

$\Delta q_{jj}$  : Additional heat in the heat balance equation

$Q_{jjse}$  : Total solar and sky radiated heat flux rate elevation corrected W/m<sup>2</sup>

$q_{jjs}$  : Heat gain rate from sun W/m

$q_{jir}$  : Radiated heat loss rate per unit length W/m

$K_{ang}$  : Wind direction factor

$k_{jj}$  : Thermal conductivity of air at temperature  $T$  film W/(m-°C)

$v$  : Speed of air stream at conductor m/s

$d_{jj}$  : Conductor diameter in mm

$\varphi$  : Angle between wind and axis of conductor

$\varepsilon$  : Emissivity

$A'_{jj}$  : Projected area of conductor per unit length m<sup>2</sup>/m

$\theta$  : Effective angle of incidence of the sun's rays degrees

$\alpha$  : Solar absorptivity (0.23 to 0.91)

$Z_1$  : Azimuth of line degrees

$Z_c$  : Azimuth of sun degrees

$H_c$  : Altitude of sun degrees

$T_{jj\text{ film}}$  : Film temperature.

$T_a$  : Ambient air temperature °C

$T_{jj}$  : Conductor temperature °C

$\Delta T_{jj}$  : Conductor temperature increment corresponding to time step °C

$T_{jj(\text{high})}$  : Maximum conductor temperature for which Ac resistance is specified °C

$T_{jj(\text{low})}$  : Minimum conductor temperature for which Ac resistance is specified °C

$T_{jj(\text{old})}$  : Conductor temperature prior to step increase °C

$\mu_{jj}$  : Dynamic viscosity of air Pa-s

$H_e$  : Elevation of conductor above sea level m

$\rho_{jj}$  : Density of air kg/m<sup>3</sup>

$S_{spc}$  : Specific heat of conductor material J/(kg-°C)

$M_{jj}$  : Mass per unit length of conductor material kg/m

$\Delta t$  : Time step used in transient calculations

$R_{jj(low)}$  : Ac resistance of conductor at minimum specified temperature.

$R_{jj(high)}$  : Ac resistance of conductor at maximum specified temperature.

$R_{jj(T_{jj})}$  : AC resistance of conductor at temperature,  $T_{jj}$   $\Omega/m$

$K_p$  : Annual demand cost of power loss (Rs. kW<sup>-1</sup>)

$K_e$  : Annual demand cost of energy loss (Rs. kWh<sup>-1</sup>)

$Loss_{(jj,k,pp)}$  : Real power loss of network branch -jj with load contribution factor.

$\Delta K_p$  : Annual growth in cost of power.

$\Delta K_e$  : Annual growth in cost of energy.

pp: Plan period in years for which the feeder is designed.

$L_f$  : Load factor.

$L_{sf}$  : Loss factor.

$\Delta L_f$  : Annual growth in loss factor.

$CC_{(jj,k)}$ : Capital investment for the conductor k of branch -jj.

$Cost_{(k)}$ : Cost of the conductor (Rs./kg/km).

$Scrap_{(k)}$ : Value of scrap material of the branch conductor after the plan period.

$F_c$  : Contribution factor

$\Delta F_c$  : Annual change in contribution factor.

$l_{(ij)}$ : Length of the conductor -jj (km).

dr: Annual discount rate.

N: Total number of nodes.

K: Node Number :1, 2, 3,..... N.

jj: Branch number :1, 2, 3,..... N-1.

$V_K$ : Sending-end voltage.

$V_{K+1}$ : Receiving-end node's voltage.

$I_{jj}$  : Branch current.

$Z_{jj}$  :  $R_{jj} + jX_{jj}$ , Branch impedance.

$P_m$  and  $Q_m$  : Real load and reactive load respectively connected to the node (m).

$S_m = P_m + jQ_m$  : Total power at node m.

$\cos \phi_{1m}$  : Present power factor.

$\cos \phi_{2m}$  : Required power factor.

$Q_{cmreq}$  : Required capacitive reactive power

$Q_{cmp}$  : Reactive power of capacitor actually placed.

$C_c$  : Cost of capacitor \$/kVAr.

$Q_{cl}$  : Reactive power of capacitor at a location (node).

$C_e$  : Cost of energy \$/kWh.

$P_{LP}$  : Real power loss of a branch.

ss: Substation node

$Q_{cmreqf}$  : Reactive power of fixed capacitor.

$Q_{cmin}$  : Minimum value of capacitor size available in inventory.

# *CHAPTER 1*

## *INTRODUCTION*

### *1.1 Introduction:*

Electricity provides a very convenient form of energy for lighting, heating, cooling, motive power for driving various types of loads and power for a number of utilization applications.

Electricity is transmitted and distributed to the consumers through transmission and distribution systems. The losses in power transmission system are small as compared to distribution system due to higher voltage level. So chances of further improvement in efficiency are bleak. Therefore, nowadays extra attention is paid to the distribution systems.

The configuration of distribution networks is quite different from transmission networks. Distribution systems are typically radial in nature. This network configuration produces low voltages at the load buses, especially those, located far away from the substation. Additionally, in a distribution system low voltages at load ends will cause large power losses and the power factor, therefore, becomes poorer than expected.

A distribution system connects consumers to high voltage transmission system. Because of lower voltage and hence higher current, the  $I^2 R$  loss in distribution system is significantly high compared to transmission system.

The modern power distribution network is constantly being faced with an ever-growing load demand. Distribution networks experience distinct change of load from a lower to higher level every day. It has been seen that above certain critical loading conditions, the distribution system experiences violation of critical loading conditions, which leads to permanent deformation of conductors. In case of several sever fault, the system voltage may collapse before the protection system clears the fault.

Line loadability and voltage collapse problems have become a point of concern for many researchers. Line loadability is a term related to steady state loading of the distribution network. Analysis of line loadability of each branch of the network shows the extent of loading of each branch under given load and most sensitive branch of the network and margin between present loading and critical loading. Voltage stability analysis is important at the time of faults or fault like situations. The protection system usually isolates the faulty portion of the network. But in some conditions the voltage collapse may occur when fault level is so high. Voltage collapse is a local phenomenon that may have consequent serious fallouts. Future increase in the demand for electric power has been projected to far exceed the planned generation of existing power system in the coming decades. This has led to increasingly complex interconnected systems that are forced to operate ever closer to the limits of loadability and stability. This operation has necessitated close examination of line loadability and voltage stability assessment capabilities of distribution systems. Many new types of instabilities are beginning to afflict the operating status of critically balanced system. The instability may be manifested in different ways, depending upon the character and configuration of the system and upon its operating mode. Of these, line loadability and voltage instability has been responsible for collapse of several major networks. Line loadability and voltage stability studies of a power distribution system are consequently essential.

Improving the performance of distribution systems to meet the required target is a matter of selecting the most cost-effective technologies and operating practices. The distribution systems tend to be very extensive with a long life span for conductors and plant. It is not sufficient to analyze how a particular portion of the network may be modified to improve its performance on date. It is a matter of determining the expected optimum solution when allowance is made for the uncertainties in the prediction of the future scenario of

customer demand. It is valuable to investigate long-term solutions especially when the implementation of the solutions may require large-scale investments. Arising from these issues, the realization by the utilities and the increasing reliance on having accurate up-to-date information for decisions on increasing revenues, improving customer service must be set up. No doubt, the vast field and organizational experience of the power utilities will continue to provide the required inputs into the total process.

To operate the distribution network near to critical loading conditions to exploit maximum benefits from installed capacity, an accurate and efficient load-flow method is necessary, to compute voltage at each node, current through each branch, branch losses, branch voltage drop and total real power losses and total reactive power losses with less computer memory utilization and less CPU time. From the above said parameters of distribution network the line loadability of each branch and voltage stability of each node of the network can be computed. The corrective measures for enhancement of critical loading like optimal conductor size selection for each branch, optimal capacitor placement and distribution network reconfiguration can be applied.

### ***1.2 Critical Loading:***

Every part of distribution network is designed to take certain load. The load equal to the maximum limit of network is called the critical load. The word 'critical load' is used for maximum limit of load that can be carried by the system because beyond this load one or more than one part of the network starts to get damaged. So the loading of the network should be within this limit. In case of distribution networks, the loadability limit is decided by the temperature of the branch conductors. The temperature of the branch conductors is a function of load current and the ambient conditions. So the critical loading limit is decided by the load current, resistance of branch conductors and ambient conditions. To increase the critical

loading limit of a distribution network, the load current for the given load and resistance of the network has to be reduced. The reduction of load current can be achieved by optimal capacitor placement and reconfiguration of network. The reduction of resistance is achieved by optimal conductor size selection for each branch of the network.

### ***1.3 Objectives of research:***

The research endeavors to derive a new load-flow solution method, a new line loadability index and voltage stability index, optimal conductor size selection method, optimal capacitor placement method and network reconfiguration method for radial distribution networks. The objectives of the research are divided into following:

- A new accurate and efficient load-flow solution method for radial networks is to be proposed. By using this load-flow solution the node voltage, branch current, branch voltage drop, branch real power losses and reactive power losses are computed.
- A new expression of line loadability index (*LLI*) is to be derived that gives the information of level of loading of each branch and the most sensitive branch of the network. The critical loading of the distribution network(s) is computed for different load models.
- A new expression for voltage stability index is to be derived that gives the information of voltage stability index of each node and the most sensitive node of the network. The voltage stability of the network(s) under fault conditions is checked for different load models.
- A new method is to be proposed to select the optimal conductor for radial distribution networks incorporating *LLI*. The critical loading and voltage stability under fault conditions of the distribution network(s) is checked for different load models.

- A new method is to be proposed for optimal capacitor placement of radial distribution networks. The critical loading and voltage stability of the distribution network(s) is checked for different load models.
- A new method is to be proposed for network reconfiguration of radial distribution networks. The critical loading and voltage stability of the distribution network(s) is checked for different load models.

#### ***1.4 Scope of research:***

After the rigorous literature survey the following areas of research are marked as the scope of further research.

- The load-flow solutions reported so far were not developed to carry out the reconfiguration of radial distribution networks without renumbering the branches and nodes. For renumbering the branches and nodes after reconfiguration needed large manual and computation effort. To save the computation effort in renumbering the branches and nodes, a new load-flow solution method that can solve the network without renumbering after reconfiguration is required.
- The term line loadability index (LLI) is used with same meaning as the voltage stability index by Juan *et al.* [41]. The new definition and formulation of line loadability index is required so that the line loadability index can be used for analysis of steady state loading condition of distribution networks.
- The voltage stability indices reported in literature had not incorporated the effect of change in resistance with the change in temperature due to flow of current through branch conductors. A new procedure and formulation for computation is required so that the effect of change in resistance with the change in temperature due to flow of current

through branch conductors can be incorporated to get the more realistic results can be obtained.

- The previous researchers had only considered the current carrying capacity of conductors as the constraint, but they did not incorporate the change in resistance or the change in current carrying capacity due to change in operating temperature of the conductors and the effect of ambient conditions on current carrying capacity of conductors. The optimal conductor size selection method can be proposed by incorporating the *LLI* as a constraint.
- Almost all previous researchers solved the capacitor placement problem according to the line reactive power demand and proposed the optimal location and size after economic analysis. Procedure for optimal capacitor placement is required to be proposed according to reactive power demand of each node. The improvement in *LLI* and *VSI* is to be investigated after capacitor placement.

The previous researchers had suggested the procedures for network reconfiguration with very much flexibility. They almost tried every possible combination for network reconfiguration but it is not possible in real distribution networks. Because it not possible to stretch tie line from any node to any other node in a distribution network. So this led to theoretical exercise but had no practical significance. A procedure for network reconfiguration is required that considers the practical constraints like seasonal change in load, maintenance of radial nature of network, same direction of flow of current as in base network and possible practically tie-lines of network reconfiguration.

### ***1.5 Organization of research:***

*Chapter 1* has presented the introduction of basic nature and problems of distribution network, critical loading, objectives of research, scope of research and organization of research.

*Chapter 2* presents the literature survey on load-flow, line loadability index and voltage stability index, optimal conductor selection, optimal capacitor placement and network reconfiguration for radial distribution networks.

*Chapter 3* presents a new load-flow solution method for radial distribution networks. The results obtained by proposed load-flow method are compared with other existing methods to show the reliability of proposed method. The comparison of computer memory and CPU time for existing and proposed method is also shown in this chapter to show the goodness of proposed method.

*Chapter 4* presents the formulation and computation of new line loadability index and voltage stability index by incorporating the change in resistance of branch conductors with the operating temperature. The results of voltage stability index are compared with the existing voltage stability indices to show the goodness of proposed method. The proposed method has been investigated for different types of load models.

*Chapter 5* presents a new method for optimal conductor size selection for radial distribution networks incorporating the line loadability index as one of the constraints. The results are compared with the existing method of optimal conductor size selection to show the goodness of proposed method. The enhancement of critical loading and voltage stability by optimal conductor placement are also shown.

*Chapter 6* presents a new method for optimal capacitor placement for radial distribution network. It is based on the node wise reactive power demand compensation. The results are compared with the existing methods to show the goodness of the proposed method. Enhancement of critical loading and improvement in voltage stability of network is investigated after optimal capacitor placement.

*Chapter 7* presents a new method for network reconfiguration based on chronological load curve. Enhancement of critical loading and improvement in voltage stability of network is investigated after network reconfiguration.

### *Chapter 8*

Conclusion and future scope of research.

*References* show the list of previous papers, books, reports etc. published by researchers those are discussed in literature survey and other chapters of this thesis on various topics related to this research.

## CHAPTER 2

### LITERATURE SURVEY

#### *2.1 Literature survey of electric power distribution networks:*

Exhaustive literature survey on the following areas

- i. Load-flow solution of electric power distribution networks.
- ii. Line loadability index and voltage stability index for radial electric power distribution networks.
- iii. Optimal conductor size selection for radial electric power distribution networks.
- iv. Optimal capacitor placement procedure for radial electric power distribution networks.
- v. Network reconfiguration for radial power distribution networks.

are shown in the following sub articles

#### *2.2 Survey on load-flow of electric power distribution networks:*

The load-flow analysis has an utmost important role for the design of distribution network. An efficient and good converging load-flow of distribution system is not only useful to obtain voltage and power loss of the network but also necessary for accurate selection of branch conductor and other aspect of planning. Load-flow methods like Newton-Raphson, and fast decoupled load-flow method proposed by Tinny and Hart [1] and Scott and Alsac [2] could be efficiently used for transmission systems having high X/R ratio. Since the distribution systems have high R/X ratio, the above methods could not converge. Some researchers Iwamoto and Tamura [3] and Rajcic and Tamura [4] suggested the modified conventional methods to solve the distribution networks. Ladder network theory was used by Kersting [5]. A compensation based method was proposed by Shirmohammadi *et al.* [6] to

solve the weakly meshed networks. The branch numbering scheme was developed to enhance the numerical performance. Baran and Wu [7] proposed a Newton –Raphson based method, which needs the computation of Jacobian matrix to solve the radial distribution networks. Hence this method needed more computational efforts. Renato [8] used the bi-quadratic equations to relate the sending-end and receiving-end voltages. But the angle of the voltage was not considered in his method. Goswami and Basu [9] proposed a direct method for solving the radial networks but they had put the limit that no node could be a junction of more than three branches. Jasmon and Lee [10] reduced the network in a single line equivalent model and used the power-flow equations in which the sending-end voltage was involved. Das *et al.* [11] proposed a unique numbering scheme for nodes and branches. They had used the simple algebraic equations to solve the radial distribution system. Haque [12] had proposed a solution method for radial and mesh power distribution networks. Backward and forward sweep technique was used for final solution. Initially the substation voltage was taken as the voltage of each node, which was updated after each successive iteration. Ghosh and Das [13] proposed a method for load-flow solution using forward backward technique. But only the magnitude of voltage at each node was computed. They had used the concept of nodes beyond branch and provided the proof of convergence. Aravindhababu *et al.* [14] proposed a technique to compute the branch currents and loads from the node branch matrix, voltage drops and node voltages were then computed. Mekhamer *et al.* [15] used the equations of Baran and Wu [7] for load-flow solution of radial distribution system but the solution methodology was different. The load of the lateral branches was supposed as the single equivalent load. After computation of the voltages of the main feeder nodes, the laterals were expanded and the voltage of the first node of the lateral was taken equal to the node voltage to which the lateral was connected. Same solution technique was used for the laterals. Eminoglu and Hocaoglu [16] presented a method for load-flow solution based on

Kirchhoff's law equations and applied the proposed method on different load models. Satyanarayana *et al.* [17] developed the load-flow equations from the ABCD parameter model of short transmission line and applied the method on the different load models. Sherpa and Ghosh [18] proposed a new algorithm for load-flow solution that needed no sequential numbering of nodes and branches, even the sending end-node and receiving-end nodes were not required if the nodes and branches are sequentially numbered. Nagaraju *et al.* [19] proposed a method for load-flow of radial distribution networks using sparse technique. But this method was only suitable for the sequentially numbered networks. If the network was not sequential numbered, manual work had to be done to make it sequentially numbered. They used the 33-node distribution network and 69-node network given in Baran and Wu [20] to show the reliability of their approach. Hamouda and Zehar [21] proposed an algorithm for load-flow solution of radial distribution networks in which branch-to-node matrix was constructed and then inverse of this matrix was formed to obtain the node-to-branch network. From node-to-branch matrix a branch matrix, was formed. Hence this method needed ample amount of computational effort and computer memory to store the matrices.

### ***2.3 Survey on line loadability index and voltage stability index of electric power distribution networks:***

In the present era the cost of erection and up-gradation of the distribution system to cope-up the load demand, are increasing day by day. The cost of energy is also shooting up. The utilities are forced by the circumstances to operate the distribution systems near to its maximum capacity. In such operating conditions, a small disturbance can cause the voltage collapse in the system. So it is very urgent to mark the maximum loadability of the system and the margin between present operating point and the maximum loadability of the distribution system. In this concern some researchers proposed the voltage stability indices,

line loadability indices and loadability margin indices. Kwatny *et al.* [22] proposed the load-flow solution using bifurcation on the point of voltage stability limit. Chiang *et al.* [23] proposed that the voltage collapse was a dynamic phenomenon. Flatabo *et al.* [24] proposed an iterative method to check the sensitivity of the system. Load was increased till the operating limit of the system reached. Clark [25] and Gupta *et al.* [26] used the P-V or Q-V curves to show the stability limit of the system. Jasmon and Lee [27] derived the voltage stability index and shown that the voltage stability limit can be computed with the help of the voltage stability index. Jacobian matrix was used to derive the voltage stability index and the margin between the operating point and the voltage collapse limit had been shown with the help of voltage stability index by Hill *et al.* [28]. Sterling *et al.* [29] used the Thevenin's equivalent of the circuit to compute the stability limit of the circuit. Gubina and Strimcnik [30] reduced the radial distribution network into the two-bus equivalent model and derived the voltage stability index from the Jacobian matrix of the reduced model. Hong and Gau [31] proposed that the study of the S-V curve could depict the stability margins of the system. They applied Newton's optimal power flow method to study the S-V curve. Mohamed and Jasmon [32] used the bus clustering technique for the voltage stability analysis, because the buses of the same type behave in same manner so that a single bus could represent the group. Cutsem *et al.* [33] showed that the voltage stability analysis was very crucial under heavily loaded systems. They had studied the operating conditions for normal and contingency conditions. Moghavvemi and Faruque [34, 35] derived the line stability index from the receiving-end reactive power equation of the reduced two-bus equivalent of the distribution network. Chakravorty and Das [36] proposed a voltage stability index, which was derived from the bi-quadratic equation of the receiving-end voltage. It was shown that the discriminant of the equation will be zero at the critical point of voltage stability. Haque [37] used the Thevenin's equivalent of the network to derive the voltage stability limit. Chaturvedi

*et al.* [38] used the Kirchhoff's law to obtain the voltage equation for the derivation of the stability index. Kataoka *et al.* [39] proposed a voltage margin proximity index considering the voltage limits of the power system. They had shown the limit of the active power to be transmitted within the operating range of the voltage. Eminoglu *et al.* [40] proposed a bus stability index using bi-quadratic equation of the receiving-end voltage of the distribution system where the smallest value of the index showed the most sensitive bus in the system. Juan *et al.* [41] used the discriminant of voltage equation as the indicator of voltage stability of the bus was under consideration. Hamada *et al.* [42] proposed a voltage stability index that had linear change in index values with the change in load. Chen *et al.* [43] derived a voltage stability prediction index from the concept of P-V curve. They also proposed the stability margin of the distribution system. The improvement of voltage stability limit was discussed by Sakthivel and Mary [44]. Hosseini [45] proposed the contingency ranking and voltage stability analysis of power system efficiently with the help of neural networks.

#### ***2.4 Survey on optimal conductor size selection for electric power distribution networks:***

Funk Houser [49] had proposed a method for economical conductor size selection for radial distribution network. They had assumed that the load was uniformly distributed throughout the network. A mathematical model had been developed by Ponnaivaiko and Rao [50] for objective function, which was to be minimized. They considered the increase in cost of energy with time as well as the change in load factor etc. and used the dynamic programming method for decision making. A dynamic model for distribution networks had been proposed by Kirn and Adler [51]. In the optimal conductor size selection procedure, the annual revenue requirements and capital requirement for energy losses were considered. That method could not be employed on large sized system. Nagendra Rao [52] proposed a new algorithm

considering the same objective function as developed by Ponnaivaiko and Rao [50]. The algorithm developed by Tram and Wall [53] based on realistic assumptions that was quite complicated. Hence software coding was a tedious task. But that method showed its limitations when used for large and complex distributions. Anders *et al.* [54] proposed a method for economical selection of cables analyzing various parameters necessarily to be considered, their effect on the economics was studied by sensitivity analysis. Leppert and Allen [55] proposed conductor selection procedure by considering load growth and wholesale power cost escalation along with the current capacity and voltage drop constraints.

Wang *et al.* [56] proposed a conductor size selection procedure with the combination of economical current density based method and heuristic approach method that showed the satisfactory results. Sivanagaraju *et al.* [57] proposed a method for selection of optimal conductor size for each branch of radial distribution network. In their method current carrying capacity as well as the minimum allowable voltage at the end nodes are taken as constraints and it was very much similar to Tram and Wall [53]. Kaur and Sharma [58] proposed a procedure for conductor size selection for radial distribution system using zero-one integer formulation of the system and formulated the skip rules to reduce the computational effort.

In the approach proposed by Kaur and Sharma [58] the method adopted for computation of voltage at each node was not clear because voltage at the nodes common for different routes would be different. The value, which would be the correct one, was not discussed. In a situation when the conductor placed in some branches were of the maximum size available in inventory and the receiving-end nodes of these branches violate the maximum voltage drop, the method suggested would upgrade the next branch where the upgradation was possible but this very branch might or might not be the right candidate branch for conductor upgradation. The term load factor has been misunderstood by the authors because it is the ratio of average load to the maximum load for a pre specified period of time. So the maximum load would

have to be served by the feeder for at least a minimum period of time. So the conductor sizes selected must be able to bear the peak load of the network. In their example of 123-node network, the proposed conductor sizes near the substation node would not be able to take that much load current.

Sivanagaraju *et al.* [57] proposed that the voltage of each node was to be checked against the minimum acceptable node voltage. Suppose an end node, or a node near the end node, violates the condition according to that approach, the conductor size of this very branch had to be upgraded. But practically it was seen that the branches at the end node were least responsible in voltage drop. So such upgradation of conductor was neither economically nor technically justified. The term load factor was also misunderstood by the authors of this paper.

The current carrying capacity of the conductor is not a constant parameter for a particular conductor, because the environment conditions and the heat generated in the conductor due to the current through it made the considerable change in the current carrying capacity. This fact has not been incorporated in any of the reported works.

In 11kV or of higher voltage feeders the connected loads were generally not the single load rather they were the group of load in the consumer premises or loads connected to 11kV/440V transformer. Usually these were not switched on simultaneously. Hence a load contribution factor was observed. Contribution factor was defined in Gonen [59]. In conductor size selection the effect of load contribution factor should be incorporated.

## ***2.5 Survey on optimal capacitor placement for electric power distribution networks:***

Reactive power compensation is an important aspect of the power distribution system, because power and energy loss reduction, power supply reliability, power quality, voltage

regulation, system capacity release can be achieved via it. The reactive power compensation is achieved with the application of shunt capacitors. Series compensation is seldom used at distribution level. As investment and benefits are associated with the reactive power compensation, so from early days of electrification many researchers and practicing engineers worked on the issue of reactive power compensation.

Initially the problem of capacitor placement was dealt for special cases with number of assumptions as proposed by Cook [60]. Duran [61] used the dynamic programming technique to deal with optimal capacitor placement problem and the capacitor sizes were taken as discrete values. Cook [62] and Chang [63] solved the capacitor placement problem by analytical approach via computer programming. Grainger and Lee [64] proposed an approach in which capacitor sizes were taken as continuous variables. They applied the non-linear programming, but the assumption to take the capacitor sizes as linear variable was unrealistic. Lee and Grainger [65] had considered the switched and fixed capacitors for reactive power compensation. Grainger and Lee [66] proposed a voltage dependent model for loss reduction and capacity release in distribution networks. Grainger *et al.* [67] suggested a real time switching scheme for reactive power control with switched capacitors. Ponnavaikko and Rao [68] considered the fixed and switched capacitors for compensation, capacity release and voltage improvement, while optimization of the load growth was also considered. Baran and Wu [7, 20] proposed a method for optimal reactive power compensation. They decomposed the problem as master and slave problem. Salama *et al.* [69] identified the sensitive node as the candidate nodes for capacitor placement with heuristics strategy. In their approach, they also considered the voltage regulator to be placed in the network. Chis *et al.* [70] used the heuristic approach for capacitor placement problem. Haque [71] proposed a method for loss reduction by capacitor placement that approach failed to recognize importance of cost and benefit constraints. Chiang *et al.* [72] suggested the global optimal solution using simulated

annealing for capacitor placement problem. Huang *et al.* [73] used tabu search algorithm and sensitivity analysis to identify the most suitable locations for capacitor placement. Miu *et al.* [74] used two-stage genetic algorithms (GA) and heuristic based algorithms for solving capacitor placement problems. Levitin *et al.* [75] proposed a genetic algorithms-based capacitor placement technique and also proposed a fast energy loss computation technique. Masoum *et al.* [76] used a Fuzzy approach for capacitor placement and sizing. They also considered the harmonics present due to non-linear loads. Das [77] proposed a Fuzzy-GA based method for capacitor sizing and location. Sarkar and Chakravorty [78] proposed an approach for capacitor placement in radial distribution networks to improve the voltage profile and loss minimization. They used the Genetic Algorithms to find the optimal location of capacitors. Goswami and Singh [79] used FACTS devices for reactive power control to minimize the voltage dip at the time of faults.

## ***2.6 Survey on network reconfiguration for electric power distribution networks:***

In earlier stage of network reconfiguration the problem was dealt to optimization of feeder cost at planning stage was proposed by Sun *et al.* [80]. Merlin and Back [81] proposed the network reconfiguration for loss reduction for distribution networks. The radial network was first converted to mesh by closing all the tie-lines and by applying branch-and-bound-type optimization technique for loss minimization so that the radial configuration was again restored. Shirmohammadi and Hong [82] proposed a technique for network reconfiguration by closing all the tie-lines first and followed the heuristic approach for optimization. However, they overcame some of the approximation made by Merlin and Back [81]. Borozan *et al.* [83] proposed a technique, which was not principally different from Shirmohammadi and Hong [82]. They incorporated in their methodology the real-time load estimation, effective determination of power loss configuration, and cost/benefit evaluation. Civanlar

*et al.* [84] used the heuristic approach for network reconfiguration but they proposed a branch-exchange technique to keep the network radial in nature throughout the procedure. They proposed that when a tie switch was closed a sectionalizing switch should be opened to keep the network radial. Baran and Wu [85] used the load-balance index and proposed the approximate load-flow method, which was used in network reconfiguration. Their method was an improvement of Civanlar *et al.* [84]. Lu *et al.* [86] proposed network reconfiguration for loss minimization in distribution networks. Taylor and Lubekaman [87] proposed a heuristic method for distribution network reconfiguration for loss reduction and capacity release of transformer and feeders. Chiang and Jean-Jumean [88, 89] and Jeon *et al.* [90] used simulated annealing algorithm for the reconfiguration. Wagner *et al.* [91] established that the heuristic approach could be used for real-time implementation for distribution network reconfiguration. Chen and Cho [92] suggested a branch-and-bound method for network reconfiguration by using binary integer programming for optimal switching scheme to loss minimization. Zhou *et al.* [93] used fuzzy technique and heuristic approach for optimization. They proposed network reconfiguration for service restoration and load balancing. They also proposed a method to minimize the operating cost of distribution network by reconfiguration. Taleski and Rajcic [94] suggested energy loss minimization by reconfiguration. Borozan and Rajakovic [95] proposed the application assessment for network reconfiguration. Lin and Chin [96] used voltage index, ohmic index, and decision index to determine the switching operation for network reconfiguration. Liu *et al.* [97] used the artificial-intelligence application for network reconfiguration. Nara *et al.* [98, 99] proposed network reconfiguration techniques for minimum loss using genetic algorithm (GA). Das [100] used the fuzzy multi objective approach using heuristic techniques for feeder reconfiguration. Huang [101] presented an evolutionary genetic algorithm (EGA)-based fuzzy multi-objective approach to solve the network reconfiguration problem by maximizing the fuzzy satisfaction

in a radial distribution system. Savier and Das [102] proposed a quadratic-loss allocation scheme for allocating losses to consumers connected to a radial distribution system before and after reconfiguration. The algorithm used was based on heuristic rule and fuzzy multi-objective approach. Bouhouras and Labridis [103] investigated the effect of load alterations in distribution systems on optimal configurations for loss minimization. The network reconfigurations were implemented utilizing heuristics techniques while load variations were simulated by stochastic procedures. Miu *et al.* [104] used the network reconfiguration for service restoration of radial distribution network in the environment of majority of manually operated switches. Kashem *et al.* [105] proposed an approach to use network reconfiguration for enhancement of voltage stability. Venkatesh *et al.* [106] proposed a fuzzy adaptation of the evolutionary programming algorithm for optimal reconfiguration due to the discrete nature of the problem for radial distribution networks to maximize loadability. González *et al.* [107] presented a heuristic reconfiguration algorithm to minimize the Non-Delivered Power of distribution networks. The thermal limits and radial nature of the network were taken as constraints.

Amanulla *et al.* [108] used the binary particle swarm optimization-based search algorithm for maximizing the reliability and minimizing the power losses. Load point reliability was evaluated by probabilistic reliability models. Zin *et al.* [109] proposed a heuristic approach for reconfiguration of radial distribution networks for minimizing the branch current. Gomes *et al.* [110] proposed a technique for network reconfiguration to achieve optimum power flow. All the switches were considered closed and a heuristic procedure was adopted to open the appropriate switches to maintain the radial nature of the network. Sarma *et al.* [111] used the reconfiguration for immediate service restoration. The candidate loads were identified by specially designed algorithm. Hong and Ho [112] proposed a method for network reconfiguration using genetic algorithms for minimizing the power loss in normal operating

conditions and minimizing the voltage drop in fault conditions. The problem was formulated as multi-objective fuzzy problem.

Fan *et al.* [113] formulated the problem as a nonlinear integer optimization problem and made it linear. They applied intuitive heuristic approach for solution. Sua *et al.* [114] suggested an ant colony search algorithm to solve the optimal network reconfiguration problem for power loss reduction using positive feedback as well as greedy search to reach the final solution. Chakravorty and Ghosh [115] investigated the effect of different configuration of distribution feeder on the reliability and contingency behavior. Remesh *et al.* [116] investigated the effect of different techniques on the loss minimization. They used network reconfiguration as a tool for loss minimization.

Rao and Narasimham [117] used the heuristic approach to suggest the best combination of switching arrangement for loss minimization. They reduced the computational effort by choosing first the tie switches having large voltage difference. Khodr *et al.* [118] used a specific approach of the Generalized Benders decomposition algorithm for reconfiguration to achieve loss minimization and load balancing in distribution networks within the applied constraints of current limit and voltage limit. Oliveira *et al.* [119] proposed a solution technique by using a mixed integer non-linear programming approach, in which a continuous function was used to handle the discrete variables. The primal–dual interior point technique was applied to solve the optimization problem at each step. The Lagrange multipliers were used to evaluate a new proposed sensitivity index for distribution system reconfiguration. Kumar and Jayabarathi [120] proposed a method based on bacterial foraging optimization algorithm for distribution network reconfiguration for loss minimization. They formulated the problem as non-linear optimization problem. The radial nature of the network was finally restored.

In all the above discussed reported work on network reconfiguration, the problem was dealt with lot of flexibility. But in practical distribution networks the chances of network reconfiguration are very limited because the distribution networks are erected in the residential, commercial, industrial areas etc. The feeders may or may not be touching each other and even some times the tie-lines cannot be stretched from any one point to another point due to various constraints. So the application of optimization techniques is not justified in this case as it leads to only theoretical exercise. However, in spite of all these constraints, still network reconfiguration is considered to optimize the available capacity of the distribution network.

## *CHAPTER 3*

### *LOAD-FLOW SOLUTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS*

#### *3.1. Introduction:*

Load-flow is an important aspect of study, analysis, planning and design of electric power distribution network. To study the above said aspects of distribution network the node voltage and its angle, branch current, real power loss and reactive power loss etc. are needed. The accuracy and reliability of study, analysis and planning of distribution network depends upon the accuracy and efficiency of load-flow method. So load-flow solution method should be efficient, reliable and should require less memory space of computer. The main aim of the chapter is to propose a new method for load-flow solution of radial distribution networks. The following features are incorporated in the proposed load-flow method.

1. No sequential numbering of nodes is required. So one or more load points can be added or eliminated from the network without the requirement of renumbering of nodes. Considerable effort for data preparation is reduced.
2. No need to store the nodes beyond the branch, the branch to node incident matrix. So the computer memory requirement is considerably reduced.
3. This method gives node voltages as well as their angle and can handle the effect of charging capacitances of the network. So this method can be used for reactive power compensation studies.

The proposed method has been tested with different types of load modeling and convergence has been obtained satisfactorily.

### 3.2. Assumptions:

It is assumed that the three-phase radial distribution networks are balanced and can be represented by their equivalent single-line diagrams. Line shunt capacitances are considered even at the distribution voltage levels.

### 3.3. Formulation of load-flow method:

Figure 3.1 shows the electrical equivalent of the radial distribution system. It is assumed that the charging capacitance of each branch is lumped at the receiving-end node of that branch.

**Fig.3.1** Two-bus equivalent of distribution network

#### 3.3.1. Derivation of expression of magnitude of voltage and angle of the voltage at each node:

The sending-end voltage can be related to the receiving-end voltage as:

$$V_k \angle \delta_k = V_{k+1} \angle \delta_{k+1} + I_{jj} Z_{jj} \quad (3.1)$$

The current through a particular branch is the sum of all load currents due to the loads connected to the nodes minus the charging current due to line shunt capacitances beyond that branch and the receiving-end node of that very branch.

$$I_{jj} = \sum_{m=k+1}^N \left[ \left( \frac{P_m - jQ_m}{V_m \angle -\delta_m} \right) + j V_m \angle \delta_m y_m^c \right] \quad (3.2)$$

$$I_{jj} = I_{jj}^a + jI_{jj}^r \quad (3.3)$$

$$I_{jj}^a = \sum_{m=k+1}^N \left\{ \frac{P_m \cos \delta_m + Q_m - V_m^2 y_m^c \sin \delta_m}{V_m} \right\} \quad (3.4)$$

$$I_{jj}^r = \sum_{m=k+1}^N \left\{ \frac{P_m \sin \delta_m - Q_m - V_m^2 y_m^c \cos \delta_m}{V_m} \right\} \quad (3.5)$$

Real and imaginary parts of the node current can be expressed as

$$I_m^a = \frac{P_m \cos \delta_m + Q_m - V_m^2 y_m^c \sin \delta_m}{V_m} \quad (3.6)$$

$$I_m^r = \frac{P_m \sin \delta_m - Q_m - V_m^2 y_m^c \cos \delta_m}{V_m} \quad (3.7)$$

$$\text{Let } Q_m' = Q_m - V_m^2 y_m^c \quad (3.8)$$

Here  $P_m$  and  $Q_m$ , are the real and reactive loads connected to the  $m$  th node.  $V_m$  and  $\delta_m$  are the voltage and its angle respectively at  $m$  th node.  $I_{jj}^a$  and  $I_{jj}^r$  are active and reactive components of the branch current ( $I_{jj}$ ). If the lengths of branches of the distribution system are considerably small compared to transmission system, the value of  $y_m^c$  will be very low. In Eq. (3.2), the charging current will also be zero. Hence the proposed method can be applied to both the cases either the charging currents are considered or neglected.

The voltage drop in each branch can be expressed by

$$I_{jj} Z_{jj} = I_{jj}^a + jI_{jj}^r \quad R_{jj} + jX_{jj} \quad (3.9)$$

So Eq. (3.1) can be expressed as

$$V_{k+1} \angle \delta_{k+1} = V_k \angle \delta_k - I_{jj}^a + jI_{jj}^r \quad R_{jj} + jX_{jj} \quad (3.10)$$

For the simplicity, the following are considered

$$C_{jj} = I_{jj}^a R_{jj} - I_{jj}^r X_{jj} \quad (3.11)$$

$$D_{jj} = I_{jj}^a X_{jj} + I_{jj}^r R_{jj} \quad (3.12)$$

$$V_{k+1} \cos \delta_{k+1} + j \sin \delta_{k+1} = V_k \cos \delta_k + j \sin \delta_k - C_{jj} + j D_{jj} \quad (3.13)$$

Separating real and imaginary parts of Eq. (3.13), we have

$$V_{k+1} \cos \delta_{k+1} = V_k \cos \delta_k - C_{jj} \quad (3.14)$$

$$V_{k+1} \sin \delta_{k+1} = V_k \sin \delta_k - D_{jj} \quad (3.15)$$

Squaring on both sides of Eq. (3.14) and Eq. (3.15), we have after addition

$$V_{k+1}^2 + 2V_{k+1}(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) + (C_{jj}^2 + D_{jj}^2 - V_k^2) = 0 \quad (3.16)$$

It is a quadratic equation of  $V_{k+1}$  and  $V_{k+1}$  can be computed as

$$V_{k+1} = \frac{-2(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) \pm \sqrt{2(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1})^2 - 4(C_{jj}^2 + D_{jj}^2 - V_k^2)}}{2} \quad (3.17)$$

$$\text{i.e. } V_{k+1} = -(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) \pm \sqrt{(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1})^2 - (C_{jj}^2 + D_{jj}^2 - V_k^2)} \quad (3.18)$$

Since the receiving-end voltage has positive value, the following root is considered.

$$V_{k+1} = -(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) + \sqrt{(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1})^2 - (C_{jj}^2 + D_{jj}^2 - V_k^2)} \quad (3.19)$$

Divide Eq. (3.15) by Eq. (3.14) we have,

$$\delta_{k+1} = \tan^{-1} \left( \frac{V_k \sin \delta_k - D_{jj}}{V_k \cos \delta_k - C_{jj}} \right) \quad (3.20)$$

### 3.3.2. Formulation of power losses:

From Eq. (3.2) and Eq. (3.8) we have,

$$I_{jj}^2 = I_{jj} I_{jj}^* = (I_{jj}^a + j I_{jj}^r)(I_{jj}^a - j I_{jj}^r) = \sum_{m=k+1}^N \left( \frac{P_m^2 + Q_m^2}{V_m^2} \right) \quad (3.21)$$

From Eq. (3.6) and Eq. (3.7), we have

$$I_m^2 = I_m I_m^* = (I_m^a + jI_m^r)(I_m^a - jI_m^r) = \left( \frac{P_m^2 + Q_m'^2}{V_m^2} \right) \quad (3.22)$$

Real power loss of branch- $jj$

$$= \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m'^2}{V_m^2} \right) R_{jj} \quad (3.23)$$

Reactive power loss of branch- $jj$

$$= \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m'^2}{V_m^2} \right) X_{jj} \quad (3.24)$$

Total real power loss of the network

$$= \sum_{jj=1}^{N-1} \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m'^2}{V_m^2} \right) R_{jj} \quad (3.25)$$

Total reactive power loss of the network

$$= \sum_{jj=1}^{N-1} \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m'^2}{V_m^2} \right) X_{jj} \quad (3.26)$$

### ***3.4. Load modelling:***

In constant power type of load model, the power demand of the load remains same irrespective to the change in terminal voltage. This is not true for most of the loads. Power demand changes with the change of terminal voltage of the loads. Due to the change in power demand of the loads with the change in terminal voltage, there is a worth noting effect on the convergence of the load-flow solution. The characteristics of exponential load models can be expressed as:

$$P = P_0 \left( \frac{V}{V_0} \right)^{n_p} \quad (3.27)$$

$$Q = Q_0 \left( \frac{V}{V_0} \right)^{n_q} \quad (3.28)$$

Here  $P_0$  and  $Q_0$  in Eq. (3.27) and Eq. (3.28) for active and reactive power respectively at nominal voltage,  $V$  and  $V_0$  stand for node voltage and nominal load voltage respectively and  $n_p$  and  $n_q$  are the respective load exponents for real and reactive power. The values of the load exponents for various types of load used by Eminoglu and Hocaoglu [16] have been presented in Table 3.1.

**Table 3.1** The values of the load exponents for various types of loads [16].

Sr. No.	Type of load	$n_p$	$n_q$
1	Battery charge	2.59	4.06
2	Fluorescent lamps.	2.07	3.21
3	Constant impedance	2.00	2.00
4	Air conditioner	0.50	2.50
5	Constant current	1.00	1.00
6	Resistance space heater	2.00	0.00
7	Pumps, fans other motors	0.08	1.60
8	Incandescent lamps	1.54	0.00
9	Compact fluorescent lamps	1.00	0.35
10	Small industrial motors	0.10	0.60
11	Large industrial motors	0.05	0.50
12	Constant power	0.00	0.00
13	Composite load = 30% constant power + 30% constant current + 40% constant impedance load.		
14	Practical load = Battery Charge 2% + Fluorescent lamps 11% + AC 8% + resistance space heating 5% + Pump, fans and other motors 18% + CFL 5% + Incandescent lamp 6% + Small motors 25% + Large motors 20%.		

### 3.5 Solution methodology:

For the load-flow solution of radial distribution network either sequential numbering scheme is adopted or non-sequential numbering scheme is followed. At first a two-dimensional array is formed through computer program, which contains the node number of link node between two interlinked laterals and the node number of first node of the linked

lateral in its each row. Next the arrays storing lateral node numbers are formed. The number of laterals' arrays is equal to the number of laterals present in the network. Main feeder, laterals and sub-laterals all are consider as laterals. Once the lateral arrays are formed, the load-flow solution can be easily carried out.

### ***3.5.1. Formation of lateral arrays:***

For any type of numbering scheme, sequential or non-sequential the following steps are used.

1. Read the sending-end nodes and receiving-end nodes.
2. Define an array  $JN[ ][ ]$  to store the junction nodes. It's a two dimensional array.
3. For every sending end node check if it appear more than once. For each repeated entry store the repeated node and its receiving end node in successive rows of the  $JN[ ][ ]$  array. The number of rows of the  $JN[ ][ ]$  array shows the number of lateral of the network.
4. Start from the substation node. Define a lateral array and put the substation node number as the first entry in the array. Check if the latest node stored in the array is the sending-end node of the next branch if YES put receiving-end node of this branch as the next entry in the lateral array. Repeat it till the condition is NO.
5. Define a lateral array to store the node numbers of the lateral. Put node numbers stored in the row under consideration of  $JN[ ][ ]$ .
6. Check if last node in lateral array is the sending end node of the next branch. If YES, put receiving-end node of this branch in the lateral array and repeat step 6. If NO, go to step 5 and repeat the above procedure till all the rows of  $JN[ ][ ]$  are considered.

The detailed procedure presented in the flow-chart of the above procedure shown in Fig. 3.2.

**Fig. 3.2** Flow Chart for formation of lateral array

### *3.5.2. Load-flow solution:*

Start from the first lateral and its first branch.

1. Consider a lateral. Compute the node current, for each of its nodes after the branch under consideration.
2. During computation of the node current it is checked whether the node under consideration is the source node of any other array. If YES, go to step 3.
3. Store first two nodes of the linked array in LN[ ][ ] array.
4. Consider the array that's first two nodes are stored in LN[ ][ ] and repeat steps 1-3 till all the entries of LN[ ][ ] are considered.
5. Compute voltage and its angle for the receiving-end node of the branch under consideration.
6. Steps 1-4 are repeated for each branch of the network.
7. Repeat the above procedures till the convergence of the load-flow solution is occurred.
8. Print the results.

The detailed procedure of the above steps is shown in Fig 3.3.

Fig. 3.3 Flow Chart for load-flow solution

### ***3.6 Convergence criteria:***

The difference of the voltage computed for any node in two successive iterations should be less than 0.00001 or  $10^{-5}$ . Proof of convergence of load-flow solution is shown in

**Appendix-A** for the proposed method.

### ***3.7 Application of the proposed method:***

To show the effectiveness of the proposed method three examples, 33-node, 69-node and 41-node radial distribution system have been considered. In first example (33-node) and second example (69-node) constant power load is considered and the effect of line shunt capacitance has been neglected. The results are compared with the existing methods. Third example (41-node) is taken to show the effect of load characteristics on convergence of load-flow solution for various types of loads and to show the effect of charging capacitances. The line data and load data of 33- node radial distribution network (Example 1) is available in Baran and Wu [7], which are shown in **Appendix-B**. Single line diagram of 33-node distribution network is shown in Fig. 3.4. The base kV and base MVA values are 12.66 kV and 100 MVA respectively. The load-flow results of 33-node radial distribution network obtained by proposed method are compared with the existing method proposed by Hamouda and Zehar [21], which is shown in Table 3.2.

The line data and load data of 69- node radial distribution network (Example 2) are available in Baran and Wu [20]. The line data and load data have been shown in **Appendix-C**. Single line diagram of 69-node distribution network is shown in Fig. 3.5. The base kV and base MVA values are 12.66 kV and 100 MVA respectively. The load-flow results are compared with the existing method proposed by Satyanarayana *et al.* [17] and have been presented in Table 3.3. Real and reactive power losses are also presented in Table 3.3. Third example is

41-node radial distribution network shown in Fig. 3.6. Line data and load data of 41-node distribution system are shown in **Appendix-D**. The technical data regarding conductors of 41-node distribution system is shown in Table D2 in **Appendix-D**. The base kV and base MVA values are 11 kV and 100 MVA respectively. Load-flow solutions have been carried out for various types of loads without considering the capacitance of the branches. The load-flow results of 41-node distribution network for different load modellings have been shown in Table 3.4, Table 3.5, Table 3.6, Table 3.7, Table 3.8 and Table 3.9. Only the magnitude of voltage and its angle, which are minimum values, are shown in Table 3.10. The corresponding node number is 13. The number of iterations required for the convergence of load-flow solution, real and reactive power losses for various types of loads are also presented in Table 3.10. Composite load consist of 30% of constant power load, 30% of constant current load and 40% of constant impedance load. Practical load consists of Battery Charge (2%) + Fluorescent lamps (11%) + AC (8%) + Resistance space heating (5%) + Pump, fans and other motors (18%) + CFL (5%) + Incandescent lamp (6%) + Small motors (25%) + Large motors (20%).

**Fig. 3.6** Single line diagram of 41-node power distribution system

**Table 3.10** Number of iterations for the convergence of the load-flow solution and the real and reactive power losses for various load models for 41-node network.

Sr. No.	Load model	No. of iterations	Real power losses in kW	Reactive power losses in kVAr	Min. voltage magnitude (p.u.) at node number 13	Angle of voltage at node number 13 in radians
1	Battery charge	4	172.8015	192.3338	0.92595	-0.01489
2	Fluorescent lamps	4	173.3655	192.9465	0.92338	-0.01485
3	Constant impedance	3	173.8920	193.5195	0.92107	-0.01275
4	Air conditioner	3	174.6066	194.2929	0.91765	-0.01909
5	Constant current	3	174.9854	194.7066	0.91610	-0.01343
6	Resistance space heater	3	174.8633	194.5766	0.91681	-0.00821
7	Pumps, fans other motors	3	175.3406	195.0899	0.91435	-0.01769
8	Incandescent lamps	3	175.1611	194.8993	0.91542	-0.00945
9	Compact fluorescent lamps	3	175.3353	195.0871	0.91457	-0.01189
10	Small industrial motors	3	175.8709	195.6667	0.91203	-0.01539
11	Large industrial motors	4	175.9700	195.7743	0.91159	-0.01532
12	Constant power	4	176.3188	196.1534	0.91005	-0.01414
13	Composite load*	3	174.8930	194.6062	0.91651	-0.01337
14	Practical load**	3	175.1937	194.9317	0.91509	-0.01503

\* Composite load = 30% constant power + 30% constant current + 40% constant impedance load.  
\*\* Practical load = Battery Charge 2% + Fluorescent lamps 11% + AC 8%  
+ Resistance space heating 5% + Pump, fans and other motors 18% + CFL 5%  
+ Incandescent lamp 6% + Small motors 25% + Large motors 20%

The proposed load-flow method is capable of handling the effect of charging capacitances of the branches. The line shunt capacitance is computed from the line data is shown lumped at the receiving end node of the respective branch in Table D1 in **Appendix-D**. Table 3.11 compares the load-flow results with charging capacitance and without charging capacitance for constant power load only. Table 3.11 shows that not only the voltage magnitude of each node, has been improved but also the angle of voltage of each node has been improved due to the inclusion of shunt capacitance. The real and reactive power losses have been reduced when the shunt capacitances are in action.

**Table 3.11** Load-flow results of 41-node system by considering the charging capacitance of the branches and without considering the charging capacitance.

Node No.	Results when capacitance is considered.		Results when capacitance is not considered.

### ***3.8 Conclusion:***

An efficient load-flow method has been proposed in this chapter. The proposed method is capable of handling the effect of charging capacitance of the branches. It is a forward sweep method in which voltage drop in each branch is computed at a voltage. The voltage of each node is computed with the recent values of voltage drop, so the convergence is confirmed in this method. The solution algorithm does not need the numbering of the nodes in sequential order. Convergence of the method is shown with different types of the load. To show the efficiency of the method, the load-flow results are compared with the existing methods for 33-node distribution network and 69-node distribution network. The CPU time and the memory requirement is less for the proposed method.

As the proposed load-flow method is capable of handling the effect of capacitance, it is suitable to be used in networks with capacitor placed at various nodes. The proposed load-flow solution method is very much suitable for reconfiguration of radial distribution networks, because it does not need renumbering of nodes for load-flow after reconfiguration, which saves lot of time and computation effort.

# *CHAPTER 4*

## *LINE LOADABILITY INDEX AND VOLTAGE STABILITY INDEX FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS*

**4.1. INTRODUCTION:** Most of the reported works in the field of line loadability index and voltage stability index have been presented in **Section 2.3** of **Chapter 2**. The term line loadability index had been used in same context as voltage stability index by Juan *et al.* [41], this term has been redefined in the present work in entirely different context. The definition of line loadability is the maximum load that can be delivered by a distribution network without violating the maximum operating temperature limits of any branch of the network. The loadability index of each branch gives the margin for further loading. The line loadability analysis is related to steady-state loading conditions. None of the previous researchers has published this type of analysis.

Voltage stability indices reported till date, analyze the maximum loading or critical loading on the basis of voltage stability. But this type of analysis is quite misleading. The voltage instability never occur in steady operating conditions, instead it always occur at the time of sever faults. But in all the reported papers the researchers studied the steady state loading conditions of distribution network through voltage stability analysis.

The voltage stability indices and loadability margins reported so far have the following major limitations:

(i) The change in resistance of the line conductor with the change in operating temperature, which is further a function of branch current, ambient temperature and weather conditions. These had not been incorporated in computation of the voltage stability indices.

(ii) Thermal limits and current carrying capacity of the branch conductors used in distribution system had been neglected while computing the loadability limits of the distribution networks. The thermal limits of the branch conductors are also dependent on ambient temperature and weather conditions.

(iii) It was not reported that for how long the distribution system was capable to withstand the heavy currents before the voltage collapse occurs or the time required by the over current protection system of the distribution network to isolate the faulty portion of the system.

Without considering these constraints, it is difficult to obtain the correct voltage stability limit and line loadability limit of the power distribution system. The voltage stability indices already available in literature compute the voltage stability limit very near or at the point where the mathematical solution of the receiving-end voltage equation was no more possible but they had not considered the change in branch conductor resistance with temperature. The effect of weather and ambient conditions were also not considered in the previous reported research work. So the value of the critical loading or the voltage stability limit was a unique one for a particular distribution network. But practically, these were not true. The weather and ambient conditions have considerable effect on the voltage stability limit and line loadability limit. So these limits are dynamic in nature.

The significance of the voltage stability index is that sometimes the load may increase instantaneously due to some load contingency or fault. The voltage collapse may occur

before the protection system comes into play or in case when the protection system fails to actuate and the line conductor attain the temperature at which material melts and lose its mechanical strength. So voltage stability index gives the loading limit under the fault or load contingency conditions. At or near the divergence point of the load-flow solution, the system is very heavily loaded that leads to higher operating temperature of the line conductors so the resistance of the conductors changes. At the higher values of resistance, the voltage drops in the branch conductors increase, specially for the constant power loads and leads to further decrease in node voltages at the critical load, this phenomenon becomes cumulative and the voltage collapse occurs well before the limit marked by the voltage stability indices, those neglect the change in resistance with higher operating temperature.

The highest operating temperature of the line conductors for steady state conditions is constrained by the annealing of the conductors and the elongation of the conductors, which leads to larger sags, small ground clearances and permanent deformation of the conductors. For ACSR conductors, the maximum operating limit for safe steady state operation is about 75 °C to 80 °C. For very short durations, the temperature can rise to 250 °C or above. The proposed line loadability index is based on this constraint of the system. Significance of the line loadability index is that it gives the steady state loadability limit of the distribution network. The steady state loading of the distribution network is limited upto that extent when the steady state temperature of at least one branch reaches the maximum steady state temperature limit.

In this chapter a voltage stability index and a line loadability index have been proposed for electrical power distribution networks. The effect of rise in temperature on resistance is

incorporated while computation of the voltage stability index and the line loadability index. Some situations have been discussed when the voltage collapse can occur although the over current protection is present there.

## 4.2. Formulation of Voltage stability index and Line Loadability index:

The voltage stability index is derived from the basic equations of distribution system to relate the sending-end voltage to the receiving-end voltage in which resistance and reactance of the branch conductors, real and reactive power loads etc are involved. The line loadability index is based on the maximum allowable temperature rise of the branch conductors.

### 4.2.1. Voltage stability index (VSI):

The sending-end voltage can be related to the receiving-end voltage as:

$$V_k \angle \delta_k = V_{k+1} \angle \delta_{k+1} + I_{jj} (R_{jj} + jX_{jj}) \quad (4.1)$$

The current in a particular branch is the sum of all load currents due to the loads connected to the nodes beyond that branch plus the load current of that branch.

$$I_{jj} = \sum_{m=k+1}^N \left( \frac{P_m - jQ_m}{V_m \angle -\delta_m} \right) \quad (4.2)$$

Here  $P_m$  and  $Q_m$  are the real and reactive loads connected to the  $(k+1)$ th node.  $V_m$  and  $\delta_m$  are the voltage and its angle at  $(k+1)$ th node. The voltage drop in each branch can be expressed by

$$V_{k+1} \angle \delta_{k+1} = V_k \angle \delta_k - \sum_{m=k+1}^N \left( \frac{P_m - jQ_m}{V_m \angle -\delta_m} \right) R_{jj} + jX_{jj} \quad (4.3)$$

For the simplicity,

$$C = \sum_{m=k+1}^N \left[ \frac{(P_m R_{jj} + Q_m X_{jj}) \cos \delta_m - (P_m X_{jj} - Q_m R_{jj}) \sin \delta_m}{V_m} \right] \quad (4.4)$$

$$D = \sum_{m=k+1}^N \left[ \frac{(P_m X_{jj} - Q_m R_{jj}) \cos \delta_m + (P_m R_{jj} + Q_m X_{jj}) \sin \delta_m}{V_m} \right] \quad (4.5)$$

$$V_{k+1} \cos \delta_{k+1} + j \sin \delta_{k+1} = V_k \cos \delta_k + j \sin \delta_k - C + j D \quad (4.6)$$

Separating real and imaginary parts in Eq. (4.6), we have

$$V_{k+1} \cos \delta_{k+1} = V_k \cos \delta_k - C \quad (4.7)$$

$$V_{k+1} \sin \delta_{k+1} = V_k \sin \delta_k - D \quad (4.8)$$

Squaring on both sides of Eq. (4.7) and Eq. (4.8), we have after addition

$$V_{k+1} = \sqrt{(C^2 + D^2 + V_k^2) - 2V_k(C \cos \delta_k + D \sin \delta_k)} \quad (4.9)$$

For the positive values of  $V_{k+1}$

$$(C^2 + D^2 + V_k^2) - 2V_k(C \cos \delta_k + D \sin \delta_k) \geq 0 \quad (4.10)$$

Let

$$VSI = (C^2 + D^2 + V_k^2) - 2V_k(C \cos \delta_k + D \sin \delta_k) \quad (4.11)$$

where

$$\delta_{k+1} = \tan^{-1} \left( \frac{V_k \sin \delta_k - D_{jj}}{V_k \cos \delta_k - C_{jj}} \right) \quad (4.12)$$

Total real power loss of the network

$$= \sum_{jj=1}^{N-1} \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m^2}{V_m^2} \right) R_{jj} \quad (4.13)$$

Total reactive power loss of the network

$$= \sum_{jj=1}^{N-1} \left( \sum_{m=k+1}^N \frac{P_m^2 + Q_m^2}{V_m^2} \right) X_{jj} \quad (4.14)$$

#### 4.2.2. Line Loadability index (LLI):

The conductors used for the distribution of electrical power have particular current carrying capacity, which is governed by the thermal limits of the material. The steady state operating temperature is assumed to be less than or equal to 80 °C.

Let the maximum operating temperature  $T_{jj(\max)}$  of the branch  $jj$ 's conductor is 80 °C.

The actual operating temperature is  $T_{jj}$ .

$$\text{Line Loadability Index } LLI = \frac{T_{jj \max} - T_{jj}}{T_{jj \max}} \quad (4.15)$$

For reliable operation of the system, value of the  $LLI$  should approach to 1. Lesser the value of  $LLI$ , lesser will be the margin for further loading of the system. The value of  $T_{jj}$  at particular load conditions changes with change in ambient temperature and weather conditions. The voltage stability limit and line loadability limit can be marked by computing both the  $VSI$  and  $LLI$ .

#### 4.3. Incorporation of change in resistance with the change in temperature:

The temperature of the conductor is considered equal to the ambient temperature when the distribution network is not energized. But when system is serving the load, heat energy is generated in the conductors, which tend to increase the temperature of the conductors. Branch conductors are exposed in the sun so that heat energy form the sun also adds its effect to increase the temperature of the conductors. As the conductors gain heat due to

above said effects, their temperature is raised from the ambient temperature. Due to the temperature difference among conductor surface and surrounding air, the heat starts dissipating in the air. Heat dissipates due to convection and radiation. The balance between heat gained and dissipated gives the final operating temperature.

It is clearly stated above that the heat is gained and dissipated by the branch conductors simultaneously. The heat balance equation comes into play. The temperature at which this equation is balanced will be the final temperature of the conductor. It takes approximately an hour to attain a final steady state temperature. The heat balance equation is very well discussed in IEEE Std. 738<sup>TM</sup>-2006 [46] with the support of explanation of various parameters and associated tables. The procedure for computation of the temperature rise of the branch conductors is discussed by Le *et al.* [47]. However, the procedure to compute the temperature rise is discussed below in brief.

Heat balance equation:

$$q_{jic} + q_{jir} = q_{jjs} + I_{jj}^2 R_{jj(T_{jj})} \quad (4.16)$$

$$q_{jic1} = \left[ 1.01 + 0.0372 \left( \frac{d_{jj} \rho_{jj} \nu}{\mu_{jj}} \right)^{0.52} \right] k_{jj} K_{ang} (T_{jj} - T_a) \quad (4.17)$$

$$q_{jic2} = \left[ 0.0119 \left( \frac{d_{jj} \rho_{jj} \nu}{\mu_{jj}} \right)^{0.6} \right] k_{jj} K_{ang} (T_{jj} - T_a) \quad (4.18)$$

$$K_{ang} = 1.194 - \cos(\varphi) + 0.194 \cos(2\varphi) + 0.368 \sin(2\varphi) \quad (4.19)$$

Equation (4.17) and Eq. (4.18) show the heat loss from the conductor due to forced convection i.e., due to wind. Eq. (4.17) shows the correct value for slow wind speed and

Eq. (4.18) shows the correct value for high wind speed. For any wind speed the higher value among both is considered.

$$q_{jcn} = 0.0205\rho^{0.5}d_{jj}^{0.75}(T_{jj} - T_a)^{1.25} \quad (4.20)$$

$$q_{jrr} = 0.0178d_{jj}\epsilon \left[ \left( \frac{T_{jj} + 273}{100} \right)^4 - \left( \frac{T_a + 273}{100} \right)^4 \right] \quad (4.21)$$

$$q_{jjs} = Q_{jyse} \alpha \sin(\theta) A'_{jj} \quad (4.22)$$

$$\theta = \cos^{-1} \cos(H_c) \cos(Z_c - Z_1) \quad (4.23)$$

$$\mu_{jj} = \frac{1.458 \times 10^{-6} (T_{jjfilm} + 273)^{1.5}}{T_{jjfilm} + 383.4} \quad (4.24)$$

$$\rho_{jj} = \frac{1.293 - 1.525 \times 10^{-4} H_e + 6.379 \times 10^{-9} H_e^2}{1 + 0.00367 T_{jjfilm}} \quad (4.25)$$

$$k_{jj} = 2.424 \times 10^{-2} + 7.477 \times 10^{-5} T_{jjfilm} - 4.407 \times 10^{-9} T_{jjfilm}^2 \quad (4.26)$$

$$T_{jjfilm} = \frac{T_{jj} - T_a}{2} \quad (4.27)$$

Equation (4.20) shows the heat loss from the surface of conductor due to natural convection. Eq. (4.21) shows the heat loss from the surface of the conductor due to radiation. Eq. (4.22) shows the heat gained by the conductor surface due to the sun radiations. When the current through conductor is increased, its temperature starts rising. It takes some time to reach the steady state value. Before reaching the steady state condition,

the heat gained by the conductor is more than the heat dissipated from the conductor.

Therefore, heat balance equation for this duration becomes

$$q_{jic} + q_{jir} = q_{jis} + I_{jj}^2 R_{jj(T_{jj})} + \Delta q_{jj} \quad (4.28)$$

$$\Delta q_{jj} = q_{jis} + I_{jj}^2 R_{jj(T_{jj})} - q_{jic} - q_{jir} \quad (4.29)$$

Heat energy gained by the conductor can be computed by dividing the total time taken to reach steady state temperature in short time intervals, i.e.  $\Delta t$  of 10 seconds for steady state operation and 0.01 or less for fault conditions.

$$\Delta t \times \Delta q_{jj} = M_{jj} \times S_{spc} \Delta T_{jj} \quad (4.30)$$

$$\Delta T_{jj} = \frac{\Delta t \times \Delta q_{jj}}{M_{jj} \times S_{spc}} \quad (4.31)$$

$$T_{jj} = T_{jj(old)} + \Delta T_{jj} \quad (4.32)$$

The formula available in IEEE Std. 738<sup>TM</sup>-2006 [46] for computation of conductor resistance at any temperature

$$R_{jj} = \left[ \frac{R_{jj(high)} - R_{jj(low)}}{T_{jj(high)} - T_{jj(low)}} \right] (T_{jj} - T_{jj(low)}) + R_{jj(low)} \quad (4.33)$$

#### ***4.4. Computation of voltage stability index and line loadability index:***

The procedural steps to compute the voltage stability index (*VSI*) and the line loadability index (*LLI*) are shown below.

(1) Read the load and line data, ambient conditions, global position of the network, time of the day, month of the year, etc.

- (2) Compute heat gained by each branch conductor due to  $I_{ij}^2 R_{ij(Tij)}$ , sun radiations and compute heat dissipated due to natural convection, forced convection and radiations for  $\Delta t$ .
- (3) Compute the changed temperature and resistance for each branch of the conductor for  $\Delta t$ .  $\Delta t = 10$  sec. for *LLI* and  $\Delta t$  can be very small as 0.01 sec in case of *VSI*.
- (4) Run the load-flow using changed resistances of branches and compute *VSI* or *LLI* or both. For load-flow solution, the Eq. (4.9), Eq. (4.12), Eq. (4.13) and Eq. (4.14) have been used.
- (5) For *LLI* the steps (2), (3), (4) are repeated for  $\sum \Delta t = 3600$  for *VSI* it can be for  $\sum \Delta t = 3600$  or the voltage collapse may occur within fraction of seconds so in this case the repetition of above procedure depends upon the time taken for voltage collapse but in this case  $\Delta t$  is taken very small.
- (6) Print the results.

#### ***4.5. Examples:***

A 30-node distribution network has been considered and shown in Fig. 4.1. The tie-lines and isolator switches shown in Fig. 4.1 are not considered at this stage. Only the base network shown with solid lines is considered. The line data and load data of the system are shown in Table E1 and Table E2 (respectively) in **Appendix-E**. Base MVA and base kV are 100 MVA and 11 kV respectively. Various aspects of behavior of the distribution networks during steady state and very heavily loaded (fault like) conditions are illustrated through this network. For load-flow studies the method proposed in **Chapter 3** is used.

**Fig. 4.1** Single line diagram of 30-node power distribution system

#### 4.5.1 *VSI at base load:*

The index values of *VSI* for the condition when all the loads connected to the nodes considered equal to their maximum demands, are shown in Fig 4.2. Table 4.1 shows the line loadability index and voltage stability index for each node at base condition for 30-node radial distribution network. It is clear from the results that the node number 21 is the most sensitive node.

**Fig. 4.2** The *VSI* of each node at normal load, resistance of each branch, current in each branch, *LLI* of each branch and real power losses in each branch at normal load for 30-node distribution network.

**Table 4.1** The index values of *LLI* for each branch and index values of *VSI* for each node at base load conditions for 30-node distribution network.

#### 4.5.2 Voltage stability limit:

The voltage stability limit of the distribution network can be computed by increasing the load on each node till the index value of *VSI* for one of the nodes becomes equal to or

approximately zero. The maximum value of  $\lambda$  is 3.5 for this particular network with CP load and *VSI* of most sensitive node (21) for this loading condition as shown in Fig.4. 3 (e). The value of the  $\lambda$  can be slightly more or less but the time taken for voltage collapse will vary inversely.

It is discussed in earlier sections of this thesis that the temperature of branch conductors increases from ambient temperature when the network is serving the load. This phenomenon is shown in Fig 4.3 (b). Width of curve shows the change, wider the curve more is the change in parameter, same is for all other parts of Fig. 4.3. With the change in temperature of branch conductor, the resistance of the branch conductors also change, which has been shown in Fig 4.3 (d).

**Table 4.2** The voltage stability index of each node and temperature of each branch at critical loading for 30-node distribution network.

Node No.	Voltage Stability Index	Branch No.	Temperature ( $^{\circ}$ C)
1	1	1	84.915
2	0.99192	2	77.795
3	0.98466	3	80.679
4	0.96852	4	73.037

29	0.95184	29	45.561
30	0.95022		

### 4.5.3. Comparison of results with existing methods:

The voltage stability index proposed by Moghavvemi and Faruque [35], Chakravorty and Das [36], Juan *et al.* [41] and Hamada [42] are computed for 30-node radial distribution network up-to voltage stability condition. The value of load multiplier  $\lambda$  beyond which the system voltage becomes instable, stability index of most sensitive node and voltage at most sensitive node are shown in Table 4.3. If the voltage stability limits computed by various voltage stability indices are compared, it is clear the existing stability indices give higher value than the proposed voltage stability. It is due to the fact that the effect of change in resistance due to change in temperature had not been incorporated in the existing voltage stability indices. Even the previous voltage stability indices are silent about the time for which the network can withstand the critical load.

**Table 4.3** Comparison of index values, voltage stability limit and minimum node voltage of 30-node distribution network.

	$\lambda^*$	Stability index	Mini. Voltage magnitude (p.u.)
Proposed <i>VSI</i>	3.5	<i>VSI</i> = 0.002845	0.386520
Moghavvemi and Faruque[35]	4.6576	$L_p = 1.000010$	0.47467
Chakravorty and Das[36]	4.6153	$SI(m_2)=0.00003$	0.43786
Juan <i>et al.</i> [41]	4.6245	$L_s = 1.00198$	0.41844
Hamada[42]	4.4567	$L_v = 1.000001$	0.50324
* multiplier of load power.			

#### ***4.6. The conditions practically possible when voltage collapse can occur in radial distribution networks:***

The voltage stability limit of a practical distribution network can never occur as it is discussed in **Section 4.5.2** due to following reasons.

- (i) The possibility of load increase in such a way that the maximum demands of all the loads are 3.5 times the original maximum demand is impractical.
- (ii) It is clear from the Fig. 4.3(e) that the voltage collapse occurred approx. 110 seconds after the step increase in  $\lambda$  from 1 to 3.5. The over-current protection of the network will trip the circuit within few seconds.
- (iii) The branch conductors cannot withstand such high temperatures for long time.

But the importance of **Section 4.5.2** is not diminished due to the above discussion, because the concept of the *VSI* and the behavior of the network are comprehensively explained through graphical representation of various parameters in this section. Moreover, **Section 4.5.3** included in the thesis to show effectiveness of the proposed method in comparison with previous methods and to show, how the previous methods are unable to compute exact voltage stability limit.

**Fig. 4.3** Results for 30-node network. Fig.4.3 (a). The voltage (p.u.) of each branch. Fig 4.3 (b). The change in resistance of each branch after loading. The *VSI* of most sensitive node. Fig 4.3(c). Change in resistance of branch conductors with change in temperature. Fig 4.3(d) The change in temperature of each branch after loading. Fig 4.3(e) *VSI* of most sensitive node (21).

Suppose the 30-node distribution network under- consideration is protected by disc type induction inverse time over-current relays. These relays give the actuation signal to vacuum circuit breakers. The choice of inverse time properties and the time delay settings are done in such a way that the relay takes some time to actuate the tripping mechanism. The time delay depends upon the inverse time characteristics of and time delay multiplier. The formula and the constants used to compute the relay operating time are discussed in details by Gers and Holmes [48]. The IEC standard inverse relay is considered and the time dial setting is taken 1 in the following discussion. The other time delays added by the

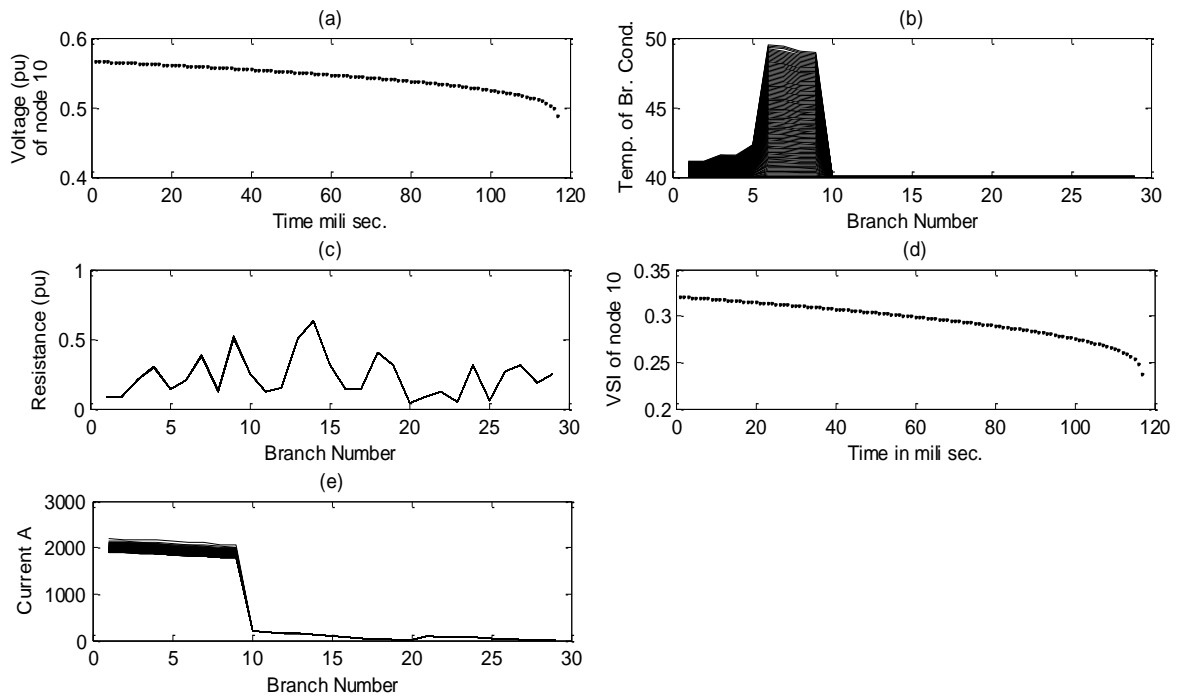

auto-recloser and circuit breaker are not considered. The pick-up current of the relay is set at 450A because the maximum expected current of the network is approximately 200A due to maximum demand of all nodes with constant power (CP) load modelling.

It is stated above that the growth of load at each node is in same proportion and up to the extent of voltage instability at most sensitive node is not possible. But a situation may arise if some fault is occurred at any point of the network and the severity of fault is such that it causes the voltage collapse prior to the protection system isolates the faulty part of the system.

In case of short circuit, the voltage collapse occurs within fraction of seconds or the protection system of the distribution network isolates the faulty portion within a very short time so that the heat generated in conductor does not dissipate in environment due to radiation and convection. During computation of temperature of each branch conductor in the above said conditions, the effect of  $q_{jic}$ ,  $q_{jir}$  and  $q_{jjs}$  are neglected.

The significance of this study is that if the voltage collapse occurs in the distribution system, it can spread in the power system also and voltage collapse in a part of distribution system can disturb the power supply of the healthy portion of the distribution system. So this study and analysis of behavior of distribution system is helpful in design of protection system.

There are three main feeders of the 30-node distribution system  $F_1$ ,  $F_2$  and  $F_3$  having nodes  $F_1=[1,2,3,4,5,6,7,8,9,10]$ ,  $F_2=[1,11,12,13,14,15,16,17,18,19,20,21]$  and  $F_3=[1,22,23,24,25,26,27,28,29,30]$ . Three situations are studied and analyzed i.e., for load suddenly increased (fault like situation in case of *VSI*) at any of the end nodes i.e. at node number 10, 21 or 30 of the network.

#### *4.6.1 Voltage stability limit for constant power load:*

The kVA load at each end node i.e. at node number 10, 21 and 30 is increased to check the voltage stability limit and the loadability limit. In this study it is considered that initially the distribution network is supplying load equal to the maximum demand of all the loads. Figure 4.4, Fig. 4.5 and Fig. 4.6 respectively show the graphical representation of results at time of voltage collapse when fault are at node 10, node 21 and node 30 with constant power load. Table 4.4, Table 4.5 and Table 4.6 show the results of voltage stability index, branch current and branch temperature for faults at node 10, node 21 and node 30 for constant load modelling.

Figure 4.6 shows the graphical representation of results at time of voltage collapse when fault is at node 30. Table 4.6 shows the voltage stability index for each node and branch current, branch temperature for critical loading at node 30. Figure 4.5 shows the graphical representation of results at time of voltage collapse when fault is at node 21. Table 4.6 shows the voltage stability index for each node and branch current, branch temperature for critical loading at node 21.

Table 4.4 shows the voltage stability index for each node and branch current, branch temperature for critical loading at node 10. Figure 4.4 shows the graphical representation of results at the time of voltage collapse when fault is at node 10. Fig. 4.5 shows the graphical representation of results at time of voltage collapse when fault is at node 30. Table 4.6 shows the voltage stability index for each node and branch current, branch temperature for critical loading at node 30. Table 4.7 shows the information about the most sensitive node, the most sensitive branch, the highest branch current in each case of fault, time taken for voltage

collapse, actuating time of relay *VSI* and *LLI* in each case of loading. The case of each end node is taken separately.

#### 4.6.2 Voltage stability limit for practical type load:

The practical distribution network supplies various types of loads. At each node the type and its percentage are considered as follows. Battery Charge (2%) + Fluorescent lamps (11%) + AC (8%) + Resistance space heating (5%) + Pump, fans and other motors (18%) + CFL (5%) + Incandescent lamp (6%) + Small motors (25%) + Large motors (20%). The values of load exponents are given in Satyanarayana *et al.* [17]. The results are shown in Table 4.7. The load added is considered as the short circuit so its load model is like the resistive load.

**Fig. 4.7** The graphical representation of results for 30-node distribution network at time of voltage collapse when fault at node 10 with practical load modelling.

**Fig. 4.8** The graphical representation of results for 30-node distribution network at time of voltage collapse when fault at node 21 with practical load modelling.

The value of loads, added at the end nodes in case of constant power load as well as practical load are the minimum values at which the voltage collapse can occur, at slightly lower values of load the protection system will actuate before the voltage collapse.

**Fig. 4.9** The graphical representation of results for 30-node distribution network at time of voltage collapse when fault at node 30 with practical load modelling.

There is a worth noting difference between the voltage stability behavior of the network having constant power load and the practical load. The practical load constitutes the voltage dependent loads but in constant power load the power demand remains same irrespective to the voltage level, so the voltage of most sensitive node in case of constant power load sinks continuously and voltage collapse occurs as shown in Fig. 4.4 (a) but when the loads and the short circuit at the end node are voltage dependent, near the point of voltage collapse the voltage of most sensitive node starts oscillate and finally voltage collapse occurs. This phenomenon is shown graphically in Fig. 4.7, Fig. 4.8 and Fig. 4.9 each of which show (a) voltage of most sensitive node, (b) change in branch resistance (p.u.), (c) branch current in ampere, (d) branch temperature in  $^{\circ}\text{C}$ , (e) voltage stability

index of most sensitive node and (f) highest branch current for faults at node 10, node 21 and node 30 respectively for practical load modelling. The oscillations are observed at the end of curve of *VSI*, voltage of most sensitive node and branch current. The reason of oscillations is that when the voltage of most sensitive node sinks the power demand of the loads reduces, this causes the voltage to cover up. But the temperature of the connecting branch is increasing. The load demand increases and consequently voltage sinks, after each oscillation. The dip in the voltage is more because of the higher temperature and resistance of the connecting branch.

#### ***4.7. Voltage stability limit and Line loadability limit for different ambient conditions:***

All the loading conditions discussed above are computed with the same set of constants related to weather and ambient temperature conditions. These constants have a vital importance in computation of *VSI* and *LLI*. But the most prominent parameters are ambient temperature and wind velocity. To show their effect on the voltage stability limit and line loadability limit, the *VSI* and *LLI* are computed for relatively low ambient temperature and high wind velocity. The results are shown in Table 4.8.

**Table 4.7** The values of *VSI* and *LLI* for loading at different end nodes for 30-node distribution network.

Node no.	<i>VSI</i> (Constant Power load)					<i>LLI</i> (Constant Power Load)		
	Value of load added (kVA)	<i>VSI</i> of most sensitive node	Time (sec)	Max. Branch current (A).	Relay actuating time (sec)	Value of load added (kVA)	<i>LLI</i> of most sensitive branch	Time (minutes)
10	11000	0.2332 node(10)	0.11	2191 Branch (1)	0.29	980	0.00737 Branch (6)	60
21	7000	0.2215 node(21)	0.17	1550 Branch (10)	0.33	210	0.00557 Branch (14)	60
30	13500	0.2384 node(30)	0.08	2550 Branch (1)	0.26	1170	0.005842 Branch (27)	60
Node no.	Value of load added in kW	<i>VSI</i> (Practical type load)				<i>LLI</i> (Practical type load)		
10	45000	0.07721 node(13)	.2	2146* Branch (1)	.3	1020	0.002337 Branch (6)	60
21	35000	0.06410 node(21)	0.25	1583 Branch (10)	0.33	250	0.0090907 Branch (14)	60
30	53000	0.078561 node(30)	0.23	2200 Branch (21)	0.28	1210	0.0041789 Branch (27)	60

\* For practical type load the value current in first branch shown in the table prevails during the oscillations otherwise its value is comparatively low as shown in Fig. 6 so the over current protection system will not respond and chances of voltage collapse are very high in this case.

**Table 4.8** The values of *VSI* and *LLI* at different ambient temperature and wind velocities for 30-node distribution network.

Value of $T_a$ and $v$	<i>VSI</i>			<i>LLI</i>		
	$\lambda$ load multiplier	<i>VSI</i> of most sensitive node(13)	Time (sec)	$\lambda$ load multiplier	<i>LLI</i> of most sensitive branch(14)	Time (minutes)
20°C and 3m/sec.	8.5	0.037621	150ms	1.95	0.001401	60
20°C and 1m/sec.	8.3	0.0091001	200ms	1.51	0.0029268	60
40°C and 3m/sec	8.2	0.012375	181ms	1.57	0.0096922	60

Accept the changes shown in this table for  $T_a$  and  $v$  the other constants have values for all the calculations in this paper i.e.  $Q_{jse}=1100$ ,  $H_e=1000$ ,  $H_c=72.5$ ,  $Z_c=139$ ,  $Z_1=90$ ,  $\alpha=0.5$ ,  $\epsilon=0.5$ ,  $\varphi=90$ ,  $T_a=40$ ,  $v=1$ .

#### 4.8. Line loadability limit:

It is previously discussed that the loadability of the distribution network is related to steady state operation. So to check the loadability limit for the loading condition under consideration, the network is loaded for the duration of one hour because within this time

**Fig. 4.10** The graphical representation of results for 30-node distribution network at time of maximum loadability limit when load of all nodes is increased with practical load modelling.

the operating temperature of branch conductors is get to be stabilized. The study of loadability limits can be significant in follow cases:

(i) In the planning stage it can be computed that how much load growth can be catered by the network.

(ii) Sometimes a situation may arise if the neighboring feeder has outage and a part of load has to be supplied by the network under consideration, it can be computed that how much load can be added to a node without violating the safe operating limits etc.

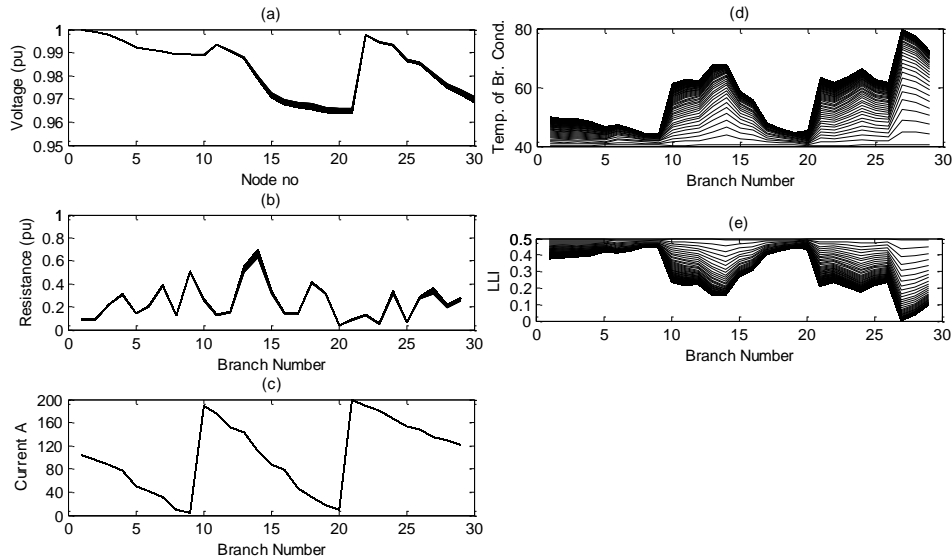

**Fig. 4.11** The graphical representation of results for 30-node distribution network at time of maximum loadability limit when load is added at node 10 with practical load modelling.

Same types of loading conditions are studied for line loadability limits those are studied for voltage stability limits. Figure 4.2 shows the *VSI* of each node, resistance of each branch, current in each branch, *LLI* of each branch and real power losses in each branch at normal load. The loadability limit of the network is checked by computing the *LLI* for each

**Fig. 4.12** The graphical representation of results at time of maximum loadability limit when load is added at node 21 with practical load modelling.

branch. Figure 4.9 shows node voltage, branch resistance, branch current, branch temperature and Line loadability index for the loadability limit occurred at  $\lambda=1.2$ . For above discussed loading, the values of *LLI* for each branch are also shown in tabulated form in Table 4.9. The results for end node loading with practical load modelling are also shown in Table 4.9. Table 4.7 shows the maximum load that can be added at node 10, node 21 and node 30 and respective line loadability index of most sensitive branch for constant power load and practical load modelling. Figure 4.11, Fig. 4.12 and Fig. 4.13 show the graphical results of end node loading for practical load modelling.

**Fig. 4.13** The graphical representation of results for 30-node distribution network at time of maximum loadability limit when load is added at node 30 with practical load modelling.

#### 4.9. Conclusion:

The proposed method in this chapter is a step ahead the previous research in the field of voltage stability studies and line loadability studies. With the incorporation of change in resistance of the branch conductors due to change in temperature makes the results more realistic and near to the practical conditions. The ability of proposed *VSI* and *LLI* to consider the effect of weather and ambient conditions has not been incorporated in any previous methods. Other novelties of the proposed *VSI* and *LLI* are that the voltage stability and line loadability of the distribution network are discussed in context of time and protection system.

# *CHAPTER 5*

## *OPTIMAL CONDUCTOR SIZE SELECTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS*

### *5.1 Introduction:*

In transmission and distribution networks line conductors is the most important part. The conductors are major component of the capital investment. Variable cost of distribution network depends upon the losses. The losses in distribution network are dependent on the conductor size. Even the critical loading limit of distribution network also depends upon the conductor size. For the enhancement of critical loading the optimal conductor sizes selection for each branch is utmost necessary. The voltage stability limit of the distribution networks can also be improved by optimal conductor placement. The fault bearing capacity and reliability are governed by the conductor size. The rigorous literature survey is shown in **Section 2.4** of **Chapter 2**. From the literature survey following gaps of previous research are identified.

Sivanagaraju *et al.* [57] proposed that the voltage of each node is to be checked against the minimum acceptable node voltage. Suppose an end node or a node nearby end node violate the condition, according to their approach conductor size of the branch feeding to this node has to be upgraded. But practically it is observed that the branches at the end node are least responsible in voltage drop. So such upgradation of conductor is neither economically nor technically justified. The term load factor is also used in different way by the authors of this paper.

In the method proposed by Kaur and Sharma [58] the method adopted for computation of voltage at each node was not clear because voltage at the nodes common for different routes would be different. The value, which would be the correct one, was not discussed. In a situation when the conductor placed in some branches were of the maximum size available in inventory and the receiving-end nodes of these branches violate the maximum voltage drop, the method suggested would upgrade the next branch where the upgradation was possible but this very branch might or might not be the right candidate branch for conductor upgradation. The term load factor has been misunderstood by the authors because it is the ratio of average load to the maximum load for a pre specified period of time. So the maximum load would have to be served by the feeder for at least a minimum period of time. So the conductor sizes selected must be able to bear the peak load of the network. In their example of 123-node network, the proposed conductor sizes near the substation node would not be able to take that much load current.

The current carrying capacity of the conductor is not a constant parameter for a particular conductor, because the environment conditions and the heat generated in the conductor due to the current through it made the considerable change in the current carrying capacity. This fact has not been incorporated in any of the reported works.

In 11kV or of higher voltage feeders, the connected loads were generally not the single load rather they were the group of load in the consumer premises or loads connected to 11kV/440V transformer. Usually these were not switched on simultaneously. Hence a load contribution factor was observed. Contribution factor was defined by Gonen [59]. In conductor size selection, the effect of load contribution factor should be incorporated.

A procedure for optimal conductor size selection has been proposed in this chapter. The limitations of previous methods are removed in the proposed method.

### ***5.2 Problem formulation:***

The problem of conductor size selection for radial distribution system is solved by incorporating the effect of change in conductor resistance with the change in temperature due to heat losses in the conductor. By incorporating this effect, the value of real power losses computed will be exact. The economical choice of conductor size also depends on the cost of energy and power. Hence the choice will be more practical and correct. The constraints of at least minimum allowable voltage at each node of the network and the loadability limit of the branch conductors are considered. The loadability limit is related to the steady state temperature and the maximum allowable temperature of the branch conductor. The conductor selection by putting this as constraint will be more practical than simply considering its current carrying capacity, which is specified in the manufacturer's data sheet.

### ***5.3 Objective Function:***

The objective function consists of cost of the conductor for each branch, cost of its scrap value at the end of the plan period, cost of the energy losses and the cost of power. The effect of improvement of load contribution factor, load factor and effect of escalation of cost of energy and power with the time are incorporated.

$$\text{Min. } F_{jj,k} = CL_{(jj,k)} + CC_{jj,k} \quad (5.1)$$

$CL_{(jj,k)}$  is the cost related to energy losses in branch-jj with k type of conductor.

$$CL_{(jj,k)} = \sum_{pp=1}^n \left[ \frac{Loss_{(jj,k,pp)} \left[ K_p \left( 1 + \Delta K_p^{pp} + 8760 K_e Lsf_{(pp)} \left( 1 + \Delta K_p^{pp} \right) \right) \right]}{1 + dr^{pp}} \right] \quad (5.2)$$

$$CC_{(jj,k)} = \left[ Cost_{(k)} I_{(jj)} - Scrap_{(k)} I_{(jj)} \right] \quad (5.3)$$

Branch Real power loss of branch jj

$$Loss_{(jj,k,pp)} = \left( \sum_{m=K+1}^N \frac{P_{(m,pp)}^2 + Q_{(m,pp)}^2}{V_{(m,pp)}^2} \right) R_{jj} \quad (5.4)$$

Total real power loss of the network for pp th year

$$= \sum_{jj=1}^{N-1} \left[ \left( \sum_{m=K+1}^N \frac{P_{(m,pp)}^2 + Q_{(m,pp)}^2}{V_{(m,pp)}^2} \right) R_{jj} \right] \quad (5.5)$$

$$P_{(m,pp)} = F_c (1 + \Delta F_c)^{pp} P_{(m,pp=1)} \quad (5.6)$$

$$Q_{(m,pp)} = F_c (1 + \Delta F_c)^{pp} Q_{(m,pp=1)} \quad (5.7)$$

#### 5.4 Constraints:

The objective function represented in Eq. 5.1 is minimized within the constraints of at least minimum allowable voltage at end nodes and line loadability index of each branch should be at least more than zero. But normally the minimum value of the line loadability index should be quite more than one for safe and reliable operation.

*(i) Minimum allowable voltage at end nodes:* It is considered that the minimum voltage level has to be maintained at the end nodes while optimal conductors for each branch are

selected. The procedure adopted is such that at first the economical conductor sizes are selected for each branch of the network. After that the voltage at the end nodes is checked if any of the end nodes violates the minimum limit, the branches at the route from substation to that very end node are identified. Then conductor size of that branch is upgraded, which has maximum voltage drop per kilometer. If the situation arises that the conductor of the candidate branch is the highest size available in inventory, the branch having next highest voltage drop per kilometer is considered and so on.

**(ii) Line Loadability Index:** Current carrying capacity of the conductor is constrained by the thermal limits of the conductor. Commonly 80°C is considered the maximum temperature for steady state loading of the overhead conductors. Beyond this temperature the tensile strength of the conductor reduces considerably and the conductor gets elongated permanently. To avoid the permanent loss of the strength and deformation of the conductor, the loading of the conductors should be within this limit and this limit is the loadability limit of the overhead conductors. It is discussed comprehensively in **Section 4.1.2 of Chapter 4**.

Let the maximum operating temperature  $T_{jj(\max)}$  of the branch- $jj$ 's conductor is 80°C.

The actual operating temperature of branch  $jj$  is  $T_{jj}$ .

$$\text{Line Loadability Index (LLI)} = \frac{T_{jj \max} - T_{jj}}{T_{jj \max}} \quad (5.7)$$

The procedure to compute conductor temperature had been discussed in Le *et al.* [47] and comprehensively in IEEE Std. 738<sup>TM</sup>-2006 [46] with associated definitions and tables of various constants and variables. However, the procedure to compute conductor temperature is discussed in brief in **Section 4.2 of Chapter 4**.

In all the previously reported work current carrying capacity of the conductors is taken as one of the constraints but taking *LLI* as the constraint is one step ahead of the reported work. A conductor may take more current in cold and windy region compared to in hot and still air.

The Line loadability index of each branch should be more than the minimum pre-defined limit for safe steady state operation of the network. After considering the voltage constraint if some branch violates the minimum *LLI* limit then the conductor of that very branch is up graded till its *LLI* is more than the minimum value.

### ***5.5 Procedural steps for optimal conductor size selection:***

- 1) Run the load-flow program using zero resistance, zero reactance of each branch and 1p.u. each node voltage. Select the conductor sizes according to their current carrying capacities. The load-flow method proposed in **Chapter 3** is used here.
- 2) Run the load-flow program, compute objective function and upgrade the conductor size if possible.
- 3) Run the load-flow program, compute objective function and upgrade or reduce the conductor size if possible to minimize the value of the objective function. Repeat this step till most economical conductor sizes are selected.
- 4) Run the load-flow program, apply the constraints and change the conductor size to avoid any violation of the constraints.
- 5) Print the results.

More detailed procedure has been presented in the flow chart as shown in Fig. 5.1.

### ***5.6 Values of various parameters used:***

While computing the conductor temperature and Line loadability index the value of various parameters related to environmental conditions and physical position of the line are shown below.

$$Q_{jse} = 1100$$

$$H_e = 1000$$

$$H_c = 72.5$$

$$Z_c = 139$$

$$Z_1 = 90$$

$$\alpha = 0.5$$

$$\varepsilon = 0.5$$

$$\varphi = 90$$

$$T_a = 40$$

$$\nu = 1.$$

The objective function is computed with the following values of various variables.

$$K_p = \text{Rs. } 5000/\text{kW}$$

$$K_e = \text{Rs. } 4.5/\text{kWh}$$

$$\Delta K_p = 0.5\%.$$

$$\Delta K_e = 0.5\%.$$

$$pp = 10 \text{ years.}$$

$$Lsf = 0.8Lf^2 + 0.2Lf$$

$$L_f = 0.5$$

$$\Delta L_f : 1\%.$$

$F_c$  = Load contribution factor = 0.4 for Example 5.1 and 0.2 for Example 5.2.

$$\Delta F_c = 1\%.$$

$\text{Cost}_{(k)}$  = Rs.130/kg/km.

$\text{Scrap}_{(k)}$  20% of  $\text{Cost}_{(k)}$ .

$$d_r = 2.15.$$

Reactance = 0.38ohm/km. For 123-node network as is used in Kaur and Sharma [58].

The conductor sizes available in inventory are enlisted in Table G2 (**Appendix-G**). These are the same sizes used by Kaur and Sharma [58].

## Conductor Size Selection Procedure

**Fig. 5.1** Flow Chart showing the procedural steps for optimal conductor size selection.

### 5.7 Examples:

To show the goodness of the proposed approach two examples of the radial power distribution networks are considered. First example is the 123-node radial distribution network. Its single line diagram, line data and load data are available in Kaur and Sharma [58]. The single line diagram is also shown in Fig. 5.2. The line data, load data and conductor sizes available in inventory are given in Table G 1 and Table G 2

(Appendix-G).

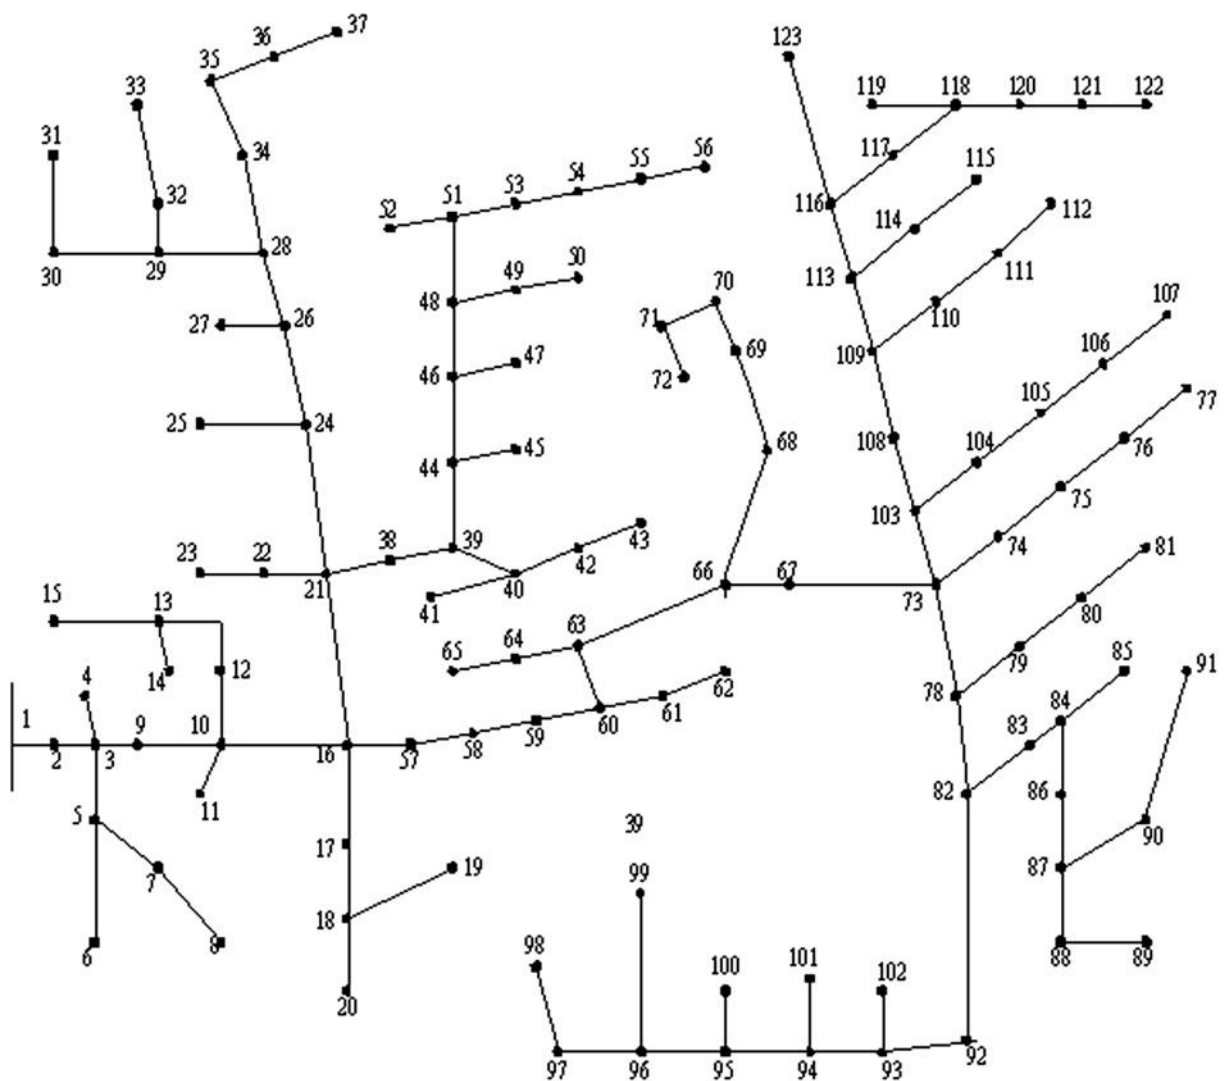

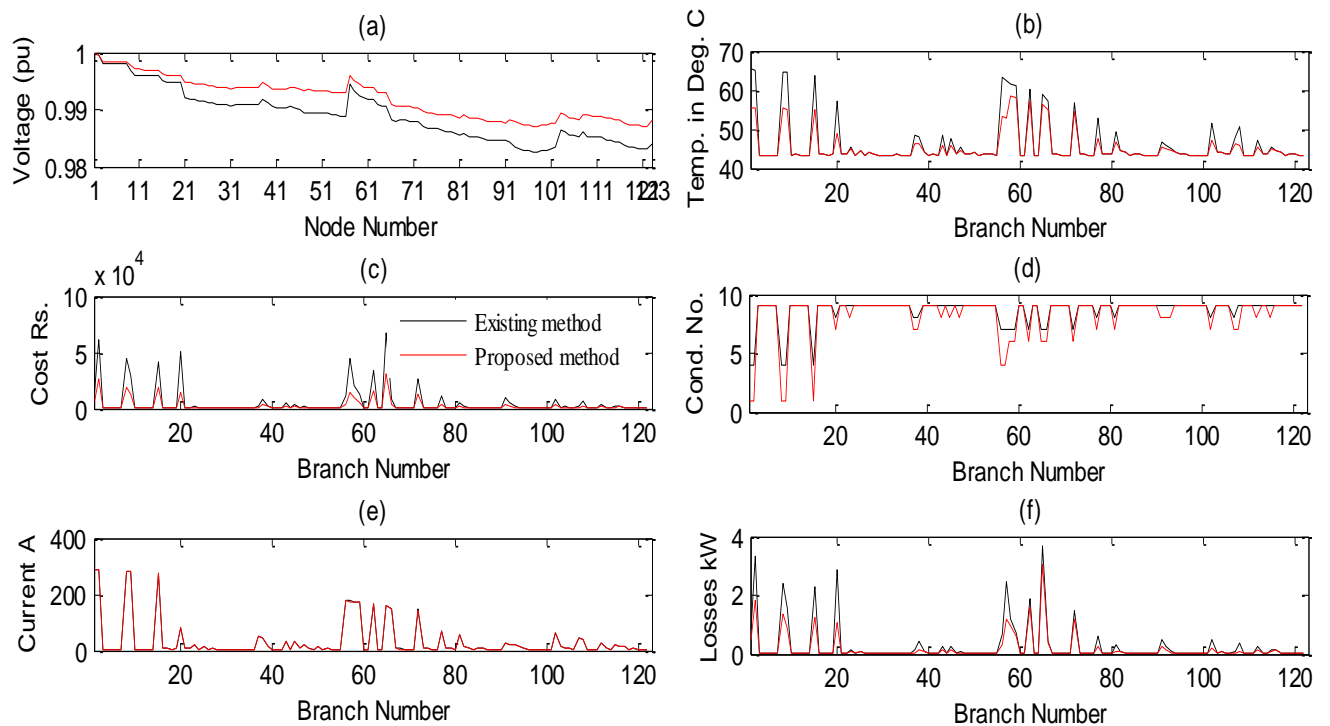

Fig. 5.2 Single-line diagram of 123-node radial distribution network [58].

The results are compared for proposed method and the existing approach regarding node voltage, branch temperature, branch wise cost, branch losses, branch current and branch wise conductor sizes. For the existing method the same conductor sizes are taken those are proposed in original work. Same inventory availability is considered. The results shown in Fig. 5.3, Table 5.1, Table 5.2, Table 5.3 and Table 5.4 reveal that for same available conductor sizes, the conductor sizes selected by proposed approach are more economical and the system is comparatively more reliable on the basis of technical aspects like node voltage, branch current, branch temperature and branch losses. The total cost for the plan period and real power losses for existing method is  $6.1064 \times 10^5$  rupees and 31.454 kW respectively. The total cost for the plan period and real power losses for existing method is  $2.8036 \times 10^5$  rupees and 19.207 kW respectively.

Real power losses =19.207 kW			

Second example is a 32-node branched radial distribution network as shown in Fig. 5.4.

The line data and load data are available in Sivanagaraju [57], which has been shown in **Appendix-F**. The results regarding node voltage, branch conductor temperature, branch wise losses, branch wise current, branch wise cost and branch wise conductor type selected are shown in Fig. 5.5, Table 5.5, Table 5.6, Table 5.7 and Table 5.8. The results of all the

aspects of the distribution network are better with the proposed approach than the existing. The total cost for the plan period and real power losses for existing method is  $5.2543 \times 10^5$  rupees and 33.214 kW respectively. The total cost for the plan period and real power losses for proposed method is  $4.85954 \times 10^5$  rupees and 32.64 kW respectively.

### *5.8 Effect of environmental conditions on Choice of conductor:*

The current carrying capacity of electrical conductors depends upon the conductor material, dimensions of the conductors and the environmental conditions. Here

environmental conditions, means ambient temperature and wind velocity and direction of wind. The temperature of conductor is a function of heat generated in conductor due to ohmic losses minus heat dissipated in surroundings. Heat dissipation mainly depends upon ambient temperature and wind velocity and wind direction. It is found that the conductor size may be lower for same power distribution for low ambient temperature and high wind region than the high temperature and low wind region. The proposed algorithm is applied for conductor size selection of 32-node system of second example for different ambient temperature and wind velocity conditions. Results shown in Table 5.9 reveal that the conductors selected at low temperature and high wind, are smaller for some branches.

### ***5.9 Effect of load modelling on choice of conductor:***

Constant power load is considered as the hardest type of load and for same load, the current is highest in constant power load. In practice loads in distribution network are not only constant power loads. Actual loads are combination of different kinds of loads. Different kinds of load models are discussed in **Chapter 3**. To show the effect of load modelling on the conductor size selection, practical load model is considered that is a combination of Battery Charge (2%) + Fluorescent lamps (11%) + AC (8%) + resistance space heating (5%) + Pump, fans and other motors (18%) + CFL (5%) + Incandescent lamp (6%) + Small motors (25%) + Large motors (20%). In Table 5.10 conductor sizes selected for the branches of 32-node distribution network are shown. It reveals that for some branches the optimal choice is smaller diameter conductor as compared to the optimal conductors selected for constant power load.

**Table 5.9** The branch conductors selected for 32-node network at different environmental conditions.

### *5.10 Enhancement of Line Loadability and voltage stability of radial distribution network by optimal conductor size selection:*

As it is discussed in the introduction part of this chapter, the loadability and voltage stability of distribution network can be improved by optimal conductor size selection. To investigate the effect of optimal conductor size selection on loadability of radial distribution network, a 30-node network is in Fig. 4.1 in **Chapter 4** is selected as a test system. The results of line loadability index and voltage stability index are investigated in **Chapter 4** before optimal conductor size selection. The results regarding loadability index, branch current, branch losses, branch temperature and cost function for base load and original network are shown in Table 5.10 and results for node voltage (p.u.) and voltage stability index for base load and original 30-node network are shown in Table 5.11. The results regarding loadability index, branch current, branch losses, branch temperature and cost function after optimal conductor size selection for 30-node network are shown in Table 5.12 and results for node voltage (p.u.) and voltage stability index after optimal conductor size selection for 30-node network are shown in Table 5.13. Figure 5.6 depicts the improvement in various parameters of 30-node network after optimal conductor size selection. Black curve is for before optimal conductor size selection and red curve for after optimal conductor size selection.

**Fig. 5.6** Comparison of various parameters i.e. Fig. 5.6 (a) comparison of node voltage (p. u.) Fig. 5.6 (b) comparison of branch temperature Fig. 5.6 (c) comparison of cost function of each branch Fig. 5.6 (d) comparison of real power losses in each branch Fig. 5.6 (e) comparison of line loadability index Fig. 5.6 (f) comparison of voltage stability index of 30-node network after optimal conductor size selection. Black curve is for before optimal conductor size selection and red curve for after optimal conductor size selection.

To investigate the improvement in line loadability and voltage stability of the radial distribution network after optimal conductor size selection, 30-node test network is selected subjected to end node loading for constant power load and practical load modelling. The results for line loadability comparison are shown in Table 5.14, which

reveals that loadability is considerably improved for each loading condition after optimal conductor size selection. Effect of optimal conductor size selection on voltage stability of the 30-node test network is investigated. Table 5.15 shows that the network is capable to withstand more sever faults at each end node. So voltage stability of test network is improved after optimal conductor size selection.

**Table 5.14** The results of line loadability index for base network and after optimal conductor selection when end nodes are heavily loaded for constant power load and practical load for 30-node distribution network.

**5.11 Conclusion:** The algorithm proposed in this chapter selects the most economical and technically more reliable conductor sizes for the branches of the radial distribution network. The constraints applied are more practical that leads to selection of more practical conductor sizes. As the change in various parameters with time like cost of energy and power, load factor, load contribution factor, practical load modelling etc. are incorporated to make the conductor selection more reliable. Enhancement of critical loading and voltage stability under fault conditions due to optimal conductor size selection is comprehensively discussed. The results give more practical insight of the various parameters of network i.e. node voltage, branch temperature, branch current etc.

# *CHAPTER 6*

## *OPTIMAL CAPACITOR SIZE SELECTION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS*

### **6.1 Introduction:**

Distribution networks used to supply the lagging power factor loads. Due to low power factor more total power has to be supplied for the required active power. This leads to higher power and energy losses and for existing installed distribution capacity, less active power can be supplied. In present days when the prices of energy are shooting up day by day, the power utilities are concentrating on power factor improvement to reduce the difference between active power and total power. The extent of power factor improvement is governed by economical benefits. Detailed literature survey regarding the topic of optimal capacitor placement is discussed in **Section 2.5 (Chapter 2)**.

In this chapter a new approach for optimal capacitor placement is proposed and it is investigated that the critical loading and voltage stability of distribution network can be increased by proper placement of shunt capacitors. Measure of loadability and voltage stability is taken the loadability index and voltage stability index proposed in **Chapter 4**. Line loadability index and voltage stability index are discussed in **Chapter 4**. For selection of optimal capacitor sizes, node-wise reactive power compensation is carried out. The locations and sizes of shunt capacitors for reactive power compensation are selected on the basis of economic benefits in the form of reduced energy losses and reduction of cost of

power of the distribution network under consideration within the voltage and power factor constraints.

## **6.2 Problem formulation:**

A capacitor generates more economical benefits when it is placed near to the load causing low power factor. So in the proposed method the reactive power compensation is dealt according to the reactive power demand at each node. The capacitor placement is also more economical when capacitor is placed at a node, which has highest value of sum of power losses from substation to the node under-consideration.

Shunt capacitors available in standard sizes, hence before taking the decision of capacitor placement at a node, it should be ensured that the reactive power demand at that node is more than or equal to the minimum capacitor size available in inventory. Capacitor placement at a node is justified if the economic benefits are more than or equal to the cost of capacitor placement within the constraint that the node power factor should not exceed unity.

Let at m th node, a load is connected of total power

$$S_m = P_m + jQ_m \quad (6.1)$$

The existing power factor of the load at m th node is  $\cos\phi_m$  where

$$\cos\phi_m = \frac{P_m}{\sqrt{P_m^2 + Q_m^2}} \quad (6.2)$$

Power factor after capacitor placement of m th node is  $\cos\phi_{2m}$  where

$$\cos\phi_{2m} = \frac{P_m}{\sqrt{P_m^2 + (Q_m - Q_{cm})^2}} \quad (6.3)$$

The reactive power demand at m th node is  $(Q_m - Q_{cm})$ .

So  $(Q_m - Q_{cm}) \geq Q_c$  at the candidate node.

### ***6.3 Economical selection of capacitor sizes:***

A cost function is developed for economic analysis of capacitor placement. As stated above capacitor placement is justified if it generates equal or more economic benefits than its cost or in other words the cost function  $F_{cl}$  is minimized.

Cost function for each capacitor location is

$$F_{cl} = Q_{cl}C_c + \left( \sum_{b=l}^{ss} P_{Lb}C_e \right) time + \sum_{b=l}^{ss} P_{Lb}C_p \quad (6.5)$$

Here  $Q_{cl}C_c$  is cost of capacitor(s) at a location,

$\sum_{b=l}^{ss} P_{Lb}$  is the sum of real power losses from sub-station to the location where the capacitor

is placed,

$C_e$  is the cost of energy and

$\sum_{b=l}^{ss} P_{Lb}C_p$  is the cost of power, which includes the cost of generation transmission and

distribution.

### ***6.4 Constraints:***

While minimizing the cost function, it should be less than unity (lagging). By maintaining this condition, the problems of over compensation and node voltage higher than the substation voltage are automatically avoided.

### ***6.5 Fixed and Switched capacitors:***

The value of fixed and switched capacitors for a network is determined by the chronological load curve. The fixed capacitors are installed to compensate the reactive

power demand at a load equal to the minimum on the chronological load curve of distribution networks.

If the data regarding the chronological load curve is not available, fixed capacitors are installed to compensate the reactive power demand for 25% of the rated load. Rest of the reactive power compensation is provided by switched capacitors.

### ***6.6 Algorithm for optimal sizing and location of shunt capacitors for radial power distribution networks:***

1. Read line data, data regarding branch conductor sizes, weather conditions, load data, required power factor, available capacitor sizes, cost of capacitor/kVAr, cost of energy, cost of power etc.
2. Run the load-flow solution program and find the real power losses, cost function and power factor at each node. Put 'don't try' flag on the nodes those do not fulfill  $(Q_m - Q_{cm}) \geq Q_c$  condition.
3. Compute  $\sum_{b=l}^{ss} P_{Lb}$  for each node and identify the node having maximum value of  $\sum_{b=l}^{ss} P_{Lb}$ .
4. Place a capacitor of minimum value at the node having maximum value of  $\sum_{b=l}^{ss} P_{Lb}$  and again repeat Step 2.
5. Compare the cost function  $F_{cl}$  for the node under consideration for before capacitor placement and after capacitor placement.
6. If cost function  $F_{cl}$  is minimized with capacitor placement then keep it with the network. Go to Step 2.

7. If cost function is not minimized, revert back the last capacitor placement and put a ‘don’t try’ flag on this node for successive iterations. Go to step 2 if all the nodes do not have ‘don’t try’ flag.
8. When all the nodes have ‘don’t try’ flag, print the results.

### ***6.7 Examples:***

Two examples of radial distribution networks are considered to show the goodness and effectiveness of the proposed method. First example is considered to compare results of proposed method with existing method. Second example is considered to show the improvement in line loadability index and voltage stability index with capacitor placement. The line loadability index gives branch wise loading limit of system in steady operating conditions and the voltage stability index gives of system stability limit in fault conditions.

#### ***6.7 Example 6.1:***

A 69-node electrical power distribution network is considered. Its line and load data has already been shown in **Appendix-C**. The results of existing method proposed by Das [100] are compared with the proposed method and presented in Table 6.1, Table 6.2 and Table 6.3. In Table 6.1 capacitor location and rating at various load conditions are shown for existing method and proposed method. Table 6.2 shows minimum voltage of 69-node network, real power losses, cost of energy losses and cost of capacitor placed for various loading conditions for existing method and proposed method. Table 6.3 shows the line power factor after capacitor placement for both methods. Comparison of results reveals that the minimum voltage at far end node and real power losses are almost comparable and there is a saving in total cost. The power factor correction is even better for the proposed

method for same capacitor step size (100 kVAr) and small capacitor step size (25 kVAr).

So the proposed method is better than the existing one.

**Table 6.1** The switching scheme of capacitors at different loads for 69-node distribution network.

Capacitor location and sizes for existing method [100]				
Location	Control setting			Optimal Size (kVAr)

The formulation of proposed method is such that the value of reactive power compensation is applied according to the reactive power demand of particular load where the capacitor is to be placed. So the step size of capacitors or capacitor sizes available in inventory should be small so that most of the loads are to be compensated. Table 6.4 and Table 6.5 show the

results of 69-node power distribution network with capacitor step size 25 kVAr instead of 100kVAr used previously. By using smaller step size cost function is further minimized and system performance is improved as compared to previous attempt.

**Table 6.4** The comparison of different parameter at various loads with existing method and proposed method for 69-node distribution network.

System parameter	Load Level existing method [100]			Proposed method.

### 6.7 Example 2:

Another example of 30-node power distribution network is considered. Line data and load data is shown in **Appendix-E** and single line diagram is shown in Fig.4.1 in **Chapter 4**.

The results of line loadability index and branch losses are shown in Table 6.6 without capacitor placement and with capacitor placement. The enhancement of line loadability limit and reduction of branch losses are observed after capacitor placement. Table 6.7 and Table 6.8 show the results for comparison of voltage stability index and node voltage, line power factor and node power factor respectively before capacitor placement and after capacitor placement. Figure 6.1 shows the results for various parameter of 30-node radial power distribution network for before capacitor placement and after capacitor placement. The parameters shown in red curve are for without capacitor placement and black curve

depicts quantities after capacitor placement. For Table 6.6 to Table 6.8 and in Fig. 6.1 the test network is under base load conditions.

### ***6.8 Enhancement of line loadability and voltage stability after capacitor placement:***

With shunt capacitor placement at or near the load terminal, there is a reduction in current from that node to substation so consequently there is a reduction in losses, temperature rise in branch conductors, improvement in voltage profile of nodes because voltage drop reduces due to reduction in current. The overall effect of capacitor placement in distribution network is that there is an enhancement in the line loadability and voltage stability. The effect of capacitor placement at normal load conditions is discussed in previous section. In this section the effect of capacitor placement under high load condition

and under fault conditions is investigated. The results for high load (up to loadability limit) at end nodes with constant power load and practical load are shown in Table 6.9.

In Table 6.10 the results of voltage stability index when fault at each end node for constant power load and practical load are shown. The results clearly indicate that there is an improvement in voltage stability after capacitor placement.

**Table 6.9** The results of line loadability index for 30-node network (after optimal conductor size selection) with and without capacitor placement when end nodes are heavily loaded for constant power load and practical load.

### 6.9 Conclusion:

A novel approach for optimal capacitor size selection and location is proposed. It is established with the support of tabulated results that the proposed approach better than the existing one. As multiple capacitor banks are placed at different locations, reliability of reactive power compensation is higher. Chances of over compensation are minimum with the proposed approach as with the variation of load at any particular node the value of switched capacitor would change accordingly. Maximum benefits of reactive power compensation are exploited from the installed capacity of capacitors. With the optimal

capacitor placement the improvement in line loadability and improvement in voltage stability are investigated and it is established with the help of tabulated results and graphical representation that the line loadability of the distribution networks and voltage stability of distribution networks can be improved by optimal capacitor placement.

## *CHAPTER 7*

### *NETWORK RECONFIGURATION FOR RADIAL ELECTRIC POWER DISTRIBUTION NETWORKS*

#### *7.1 Introduction:*

In previous chapters it has been discussed how to enhance the loadability limit and voltage stability limit of radial distribution networks by optimal conductor size selection and capacitor placement. In this chapter, it is discussed how the already installed capacity can be best utilized to increase the loadability limit and voltage stability limit by network reconfiguration. Detailed literature survey is discussed in **Section 2.6 (Chapter 2)**. In all the discussed reported work on network reconfiguration, the problem was dealt with lot of flexibility. But in practical distribution networks the chances of network reconfiguration are very limited because the distribution networks are erected in the residential, commercial, industrial areas etc. The feeders may or may not be touching each other and even some times the tie-lines cannot be stretched from any one point to another point due to various constraints. The application of optimization techniques is not justified in this case because it leads to only theoretical exercise. However, in spite of all these constraints, network reconfiguration is considered to optimize the available capacity of the distribution network.

In this chapter an attempt has been made to establish that the reconfiguration of networks can be carried out for load balancing during the seasonal change in load depicted by the chronological load curves of the feeders. None of the previous researchers had proposed this type of approach. Usually same type of loads are concentrated in particular

areas like the feeders dedicated to supply residential areas, the dominated loads are domestic and commercial, some feeders may be dominated with industrial loads, some with agriculture etc. By examining the chronological load curves, the possibilities of feeder reconfiguration can be identified.

### ***7.2 Problem formulation:***

The first step is to find the chances of network reconfiguration and the location of tie-switches, is to draw the annual chronological load curves of the candidate feeders or laterals. By examining the annual chronological load curves and the location of feeders, the position of tie lines, the switching scheme can be developed. While fixing the location of tie-lines and developing the switching schemes, the line loadability limits of the feeders or lateral should not be violated. For example only that much load should be shifted to some feeder from some other feeder so that the receiving feeder's current carrying capacity should not be violated. It is assumed for simplicity that the length and the type of conductor of tie-line is same as that branch which is disconnected by corresponding isolating switch.

### ***7.3 Constraints:***

At the time of reconfiguration procedure following points should be taken as constraints.

1. Only the practically possible locations of tie-lines should be considered. Because mostly it is not possible to set a tie-line to connect any two locations of the distribution network.
2. The line loadability index should be maximized.
3. Radial nature of the network should be maintained. When a tie line is connected, an isolator switch is opened to avoid mesh configuration.

4. Direction of flow of current through branches should be same as before reconfiguration. This is necessary because the conductor sizes of branches are selected according to the current through branches, if the direction of current is reversed, there are chances that a branch which was the last branch of a lateral becomes the first branch of lateral so it has to feed more loads so that the current carrying capacity can be violated.

#### ***7.4 Procedural Steps for network reconfiguration:***

1. Draw the annual chronological load curve for each lateral from annual load data.
2. By approximation make the curves in discrete form.
3. Identify the locations of tie-lines between laterals or feeders which are practically possible.
4. Identify the most suitable options of tie-lines by computation of load-flow solution and line loadability index.
5. Develop the annual switching scheme for tie-lines from Step 4.
6. Print the results

#### ***7.5 Example:***

An example of 30-node typical Indian radial distribution network is considered to illustrate the proposed procedure for network reconfiguration for enhancement of loadability of the radial distribution networks. Line data and load data is given in **Appendix-E**. Single line diagram of 30-node radial distribution network is shown in Fig. 7.1. The value of base voltage is 11kV and value of base power is 100 MVA. There are three laterals of distribution network. Lateral 1 is dedicated to serve industrial load. The industrial load is considered to be the agriculture based industry like cotton mills,

sugar mills and rice mills. Industrial load consists of 50% large industrial motors + 10% compact florescent lamp + 10% air conditioner + 20% small industrial motor load + 10% pump set and fan load.

Lateral 2 is dedicated to serve residential and commercial loads. The domestic and commercial load consists of 20% florescent lamps+ 15% incandescent lamp + 30% air conditioner load + 15% resistance space heater + 30% pump set and fan.

Lateral 3 is dedicated to serve agriculture load. Agriculture load consists of 95% pump set load + 5% incandescent lamp load. The load exponents for various loads are shown in Chronological load curves, which are developed from the annual load data of the laterals, as shown in Fig. 7.2. Curve 1 depicts the domestic load. Domestic load is high in India during summer season (June to September). Curve 2 shows the monthly percentage load for agriculture load dominated in lateral. The agriculture load is high during paddy season from May to September. Curve 3 is for agriculture based industrial load, which is also a seasonal type of load. Figure 7.3 shows the approximated chronological load curves for 30-node radial distribution network. To improve the load factor the service utility encourages such industry to use more power in off-peak months. So the load on such feeders is high during winter season. Looking at the approximated chronological curves shown in Fig 7.3 it is evident that the load can be shifted seasonally from one lateral to another.

To show the benefits and effectiveness of network reconfiguration the 30-node test network is considered in its base form which means without optimal conductor size selection and without capacitor placement. All the possible options for reconfiguration are tried and the results of beneficial seasonal reconfigurations are shown. The comparison of

various parameters like minimum node voltage, minimum voltage stability index, minimum line loadability index and total real power losses of the network before and after reconfiguration are shown in Table 7.1. Table 7.1 also shows the status of tie-lines and isolator switches during each season. Table 7.2, Table 7.3 and Table 7.4 show the comparison of results regarding *LLI*, *VSI*, node voltage and branch power losses for 30-node distribution network from January to April, May to August and September to December respectively without optimal conductor size selection and capacitor placement. Same results are shown in graphical form with the help of Fig. 7.4, Fig. 7.5 and Fig. 7.6 respectively.

The beneficial reconfiguration options are searched through the proposed algorithm after optimal conductor size selection and capacitor placement. The optimal conductor sizes selected for 30-node test network are discussed in **Chapter 5** (Table 5.12). The values of total capacitors on in every season are shown in Table 7.9. The tie-lines and isolator switches status is shown in Table 7.5. The tie-lines' and isolator switches' status is same for January to April and September to December for base network and for network with optimal conductor size selection and capacitor placement. But for the duration of May to August in base network no reconfiguration is beneficial due to the fact that the conductors for lateral 2 are under size. But after optimal conductor size selection and capacitor placement during May to August, the reconfiguration is beneficial and the status of tie-line and isolator switch has been shown in Table 7.5. The detailed results are shown in tabular form from Table 7.6 to Table 7.9 and in graphical form in Fig. 7.7 to Fig. 7.9.

## ***7.6 Conclusion:***

From the above discussion it can be concluded that rather the chances for reconfiguration are very limited in case of distribution networks but it has great benefits in the form of reduced losses, increased line loadability, increased voltage stability, reduced branch current and improved voltage profile of the network after reconfiguration. Along with these benefits the reliability of supply is increased. At the time of outage, supply of some portion of network can be restored. Through network reconfiguration the already installed capacity can be best used. The line loadability and voltage stability of the distribution networks can be enhanced. The tabulated results and graphical represented that the critical loading and voltage stability of the 30-node test network has been improved. The proposed approach is novel no such approach in the field of network reconfiguration is reported so far.

# *CHAPTER 8*

## *MAIN CONCLUSION AND FUTURE SCOPE OF WORK*

The aim of this chapter is to give the overall conclusion of the thesis and to show the future scope of work. In this chapter the results and findings of each chapter are to be discussed.

### *8.1 Main conclusion:*

A brief introduction of distribution networks, introduction of critical loading, objectives of research, scope of research and organization of research are discussed in **Chapter 1**. The detailed literature survey of load-flow solution for distribution networks, line loadability index and voltage stability index for radial distribution networks, optimal conductor size selection for radial distribution networks, optimal sizing and location of shunt capacitors for radial distribution networks and reconfiguration of distribution networks is discussed in **chapter 2**.

A new and efficient load-flow method is proposed in **chapter 3**. The algorithm of load-flow method is developed in such a way that it does not require the sequential numbering of node and branches. The nodes of each lateral are identified from the line data through the computer program and the load-flow is carried out by using these lateral arrays. The equations of load-flow solution are capable to take the effect of charging capacitances. So this load-flow solution method is very suitable for load-flow of distribution networks having capacitors installed at various nodes. Due to non-requirement of sequential node numbering and branch numbering this load-flow solution method is also very suitable for network reconfiguration. The efficiency and reliability of the proposed method is established by comparing the results of proposed method with the existing methods [17] and [21] for 69-node distribution network and 33-node distribution network respectively. It is observed that the cpu time and

memory requirement is quite less for the proposed method. The proposed load-flow method is used in this work for load-flow solution in subsequent chapters. The convergence of load-flow solution is also checked for various load models.

In **chapter 4** a new definition is proposed for line loadability index for radial distribution network. The line loadability index is related to the operating temperature of the branch conductors. The steady state of operating condition and the steady state critical loading condition of the distribution network are studied and analyzed through line loadability index. By the analysis of line loadability index the most sensitive branch of the distribution network and other weak branches can be identified. A voltage stability index is proposed in this chapter. The voltage stability index can be used to find the voltage stability limit of the distribution network under fault conditions. Most sensitive node of the network can be identified by voltage stability index. While computing the voltage stability index for each node of the distribution network the effect of change of resistance due to change of temperature is incorporated. Through line loadability index and voltage stability index the steady state conditions of the distribution network and the network conditions under the fault conditions can be analyzed. In **chapter 4** the line loadability analysis and voltage stability analysis is shown with the help of tabulated results and graphical representations. With the help of voltage stability index the minimum severity of fault can be computed for which there are chances of voltage collapse will occur, before the protection system of the distribution network will respond to clear the fault. With the help of line loadability index the maximum loading limit of the distribution network can be found.

In **chapter 5** a new method for optimal conductor size selection for radial distribution networks is proposed, and the enhancement of critical loading and enhancement of voltage stability is achieved by optimal conductor size selection. In the conductor size selection procedure the effect of change in resistance due to change in temperature caused by flow of current through conductor is incorporated.

To show the goodness and reliability of the proposed method the results of optimal conductor size selection for existing methods [57] and [58] are compared with the proposed method. The proposed method showed the better results in every respect. The enhancement in critical loading and improvement in voltage stability are shown with the help of tabulated results and graphical representations.

In **chapter 6** the optimal capacitor placement method is proposed. The power factor improvement is achieved by placing the optimal sizes of capacitors at nodes where the reactive power compensation is required. Almost all the methods discussed in literature survey used the line reactive power compensation but in proposed the reactive power compensation is achieved by node reactive power compensation. The comparison of results with the existing method [100] is shown in tabulated form and it is established that the proposed method for reactive power compensation by shunt capacitors is better than the proposed method, because with less capacitor cost higher economical benefits can be achieved. Even the power factor improvement is also better with the proposed method. It is also shown with the help of tabulated results and graphical representations that the enhancement of critical loading of radial distribution network and improvement of voltage stability of radial distribution network can be achieved by reactive power compensation.

In **chapter 7** the enhancement of critical loading and improvement in voltage stability is achieved through network reconfiguration of radial distribution network. The possibilities of network reconfiguration are identified through the investigation of chronological load curve. There is a seasonal change in load demand of different kind of consumers. So the load from a lateral having high load demand can be shifted to the lateral having low load demand. This procedure is applied to a typical distribution 30-node distribution network having three lateral dedicated to different types of loads. The enhancement of critical loading and improvement of voltage stability are shown with the help of

tabulated results and graphical representations. The proposed method is based on the practical constraints of network reconfiguration.

The enhancement of critical loading and improvement in voltage stability is achieved after each step i.e. optimal conductor size selection, capacitor placement and network reconfiguration.

### ***8.2 Future scope of research:***

After carrying out the extensive research work it realized that the present research work can be extended in following directions.

- In this work it is assumed that the distribution network is balanced so the research work can be extended for three phase unbalanced distribution networks. So load-flow solution method for unbalanced three phase distribution networks has to be developed.
- This work is oriented for radial distribution network in further research can be extended for the weakly meshed and meshed distribution networks.
- The network line loadability and voltage stability can be investigated in the environment of smart grid.
- In the present work the static load modelling is considered the effect of dynamic load modelling on critical loading of distribution network and voltage stability of distribution network can be investigated.

The effect of online voltage controller can be incorporated in the investigations of critical loading and voltage stability studies.

## *Appendix-A*

### 3.6 Proof of convergence:

It is mathematically established in this section of the thesis that the formulation proposed in **Section 3.3 (Chapter 3)** has a surety of convergence. This is because the voltage that is being calculated in the ongoing iteration depends upon the voltage and the voltage drop calculated in the previous iteration. The voltage drop in any branch is also a function of the previous iteration voltage. Figure A1 graphically shows the convergence of the load-flow solution.

From Eq. (3.14) and Eq. (3.15) of **Chapter 3**

$$V_{k+1} \cos \delta_{k+1} + C_{jj}^2 + V_{k+1} \sin \delta_{k+1} + D_{jj}^2 = V_k \cos \delta_k^2 + V_k \sin \delta_k^2 \quad (\text{A1})$$

By rearranging Eq. (A1)

$$V_{k+1}^2 + 2V_{k+1}(C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) + (C_{jj}^2 + D_{jj}^2) = V_k^2 \quad (\text{A2})$$

$$\text{Let } V_{k+1}^2 + \Delta V_{jj} = V_k^2 \quad (\text{A3})$$

$$V_{k+1}^2 \left( 1 + \frac{\Delta V_{jj}}{V_{k+1}^2} \right) = V_k^2 \quad (\text{A4})$$

$$V_{k+1} \left( 1 + \frac{\Delta V_{jj}}{V_{k+1}^2} \right)^{\frac{1}{2}} = V_k \quad (\text{A5})$$

$$V_{k+1} \left( 1 + \frac{\Delta V_{jj}}{2V_{k+1}^2} \right) = V_k \quad (\text{A6})$$

$$V_{k+1} = V_k - \frac{\Delta V_{jj}}{2V_{k+1}} \quad (\text{A7})$$

$$V_{k+1} = V_k - \frac{\Delta v_{jj}}{V_{k+1}} \quad (\text{A8})$$

Here

$$\Delta v_{jj} = \frac{V_{jj}}{2} = V_{k+1} (C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) + \frac{1}{2} (C_{jj}^2 + D_{jj}^2) \quad (\text{A9})$$

$$\frac{\Delta v_{jj}}{V_{k+1}} = C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1} + \frac{C_{jj}^2 + D_{jj}^2}{2V_{k+1}} \quad (\text{A10})$$

From Eq. (A8) and Eq. (A10)

$$V_{k+1} = V_k - (C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) - \left( \frac{C_{jj}^2 + D_{jj}^2}{2V_{k+1}} \right) \quad (\text{A11})$$

$C_{jj}$  and  $D_{jj}$  has link with  $V_{k+1}$  and the nodes beyond the node under consideration. Hence convergence of  $V_{k+1}$  gives assurance the convergence of the  $V$ 's of the other nodes beyond this node. In this case the solving of  $V_{k+1}$ , the present value of  $V_k$  and the past value of  $V$ 's of  $m=k+1$ th node and nodes beyond this are used.

$$\text{Let } g(V_{k+1}) = V_k - (C_{jj} \cos \delta_{k+1} + D_{jj} \sin \delta_{k+1}) - \left( \frac{C_{jj}^2 + D_{jj}^2}{2V_{k+1}} \right) \quad (\text{A12})$$

Hence  $C_{jj}$  and  $D_{jj}$  are functions of  $f\left(\frac{1}{V_m}\right)$  where  $m=k+1, k+2, \dots$

In the above graph shown in Fig. A1  $V_{k+1}(0)$  is the initial value of  $V_{k+1}$ .  $V_{k+1}(n)$  and  $V_{k+1}(n+1)$  are the value of  $V_{k+1}$  at the  $n$ th and  $n+1$ th iteration respectively  $\xi_{k+1}$  is the final value of  $V_{k+1}$ .

$$\text{Here } \varepsilon_{k+1}(n) = V_{k+1}(n) - \xi_{k+1} \quad (\text{A13})$$

$$\text{and } \varepsilon_{k+1}(n+1) = V_{k+1}(n+1) - \xi_{k+1} \quad (\text{A14})$$

$$V_{k+1}(n) = \varepsilon_{k+1}(n) + \xi_{k+1} \quad (\text{A15})$$

$$\text{And } V_{k+1}(n+1) = \varepsilon_{k+1}(n+1) + \xi_{k+1} \quad (\text{A16})$$

$$V_{k+1} \ 1 = g \ V_{k+1} \ 0 \quad (\text{A17})$$

$$V_{k+1} \ 2 = g \ V_{k+1} \ 1 \quad (\text{A18})$$

$$V_{k+1} \ 3 = g \ V_{k+1} \ 2 \quad (\text{A19})$$

:

:

$$V_{k+1} \ n+1 = g \ V_{k+1} \ n \quad (\text{A20})$$

$$\xi_{k+1} + \varepsilon_{k+1} \ n+1 = g \ \xi_{k+1} + \varepsilon_{k+1} \ n =$$

$$\xi_{k+1} + \varepsilon_{k+1} \ n \ g' \ \xi_{k+1} + \frac{1}{2!} \varepsilon_{k+1}^2 \ n \ g'' \ \xi_{k+1} + \dots \quad (\text{A21})$$

$$g' \ \xi_{k+1} = \frac{\Delta v_{ij}}{V_{k+1}^2} \quad (\text{A22})$$

**Fig. A1** Plot of  $g\{V_{k+1}\}$  v/s  $V_{k+1}$

$$g'' \xi_{k+1} = \frac{-2\Delta v_{jj}}{V_{k+1}^3} \quad (A23)$$

For  $V_{k+1} = \xi_{k+1}$ , (A24)

$$g' \xi_{k+1} = \frac{\Delta v_{jj}}{\xi_{k+1}^2} \quad (A25)$$

$$g'' \xi_{k+1} = \frac{-2\Delta v_{jj}}{\xi_{k+1}^3} \quad (A26)$$

$$\text{So } \varepsilon_{k+1}(n+1) = \varepsilon_{k+1}(n) \left( 1 - \frac{\varepsilon_{k+1}(n)}{\xi_{k+1}} \right) \frac{\Delta v_{jj}}{\xi_{k+1}^2} = \varepsilon_{k+1}(n) \left( 1 - \frac{\varepsilon_{k+1}(n)}{\xi_{k+1}} \right) g' \{ \xi_{k+1} \} \quad (A27)$$

Since  $\frac{\varepsilon_{k+1}(n)}{\xi_{k+1}}$  can be neglected,

$$\varepsilon_{k+1}(n+1) = \varepsilon_{k+1}(n) g' \{ \xi_{k+1} \} \quad (A28)$$

Since the  $\sin \delta_{k+1}$  and  $\cos \delta_{k+1}$  are approximately equal to 0 and 1.  $\Delta v_{jj}$  becomes

$\Delta v_{jj} = V_{k+1} C_{jj} + \frac{1}{2} C_{jj}^2 + D_{jj}^2$ . Which is function of R, X, P and Q. Hence the convergence

of the proposed method becomes linear in this case and  $\Delta v_{jj}$  becomes very small and

hence  $g' \xi_{k+1}$  less than 1. This gives the guarantee of the convergence of the proposed

method.

**Table D 2** Technical data of the conductors used in 41-node distribution system

Cond. type.	Code name.	Dia. Of cond. (mm)	Area of X-section.(mm <sup>2</sup> ) Nominal Copper area Sq. mm.	Resistance (ohm/km)	Reactance (ohm/km)	Max. Current carrying capacity (amp.) at 45° C ambient temp.
1	Squirrel	6.33	12.90	1.3760	0.3896	107
2	Weasel	7.77	19.35	0.9810	0.3797	139
3	Rabbit	10.05	32.26	0.5441	0.3673	193
4	Raccoon	12.27	48.46	0.3657	0.3579	250
5	Dog	14.15	65	0.2745	0.3112	300
6	Lion	22.26	140	0.1223	0.2446	515

The spacing between the two conductors is 1.2 meter. System voltage is 11kV. Power factor is 0.8. Base voltage = 11kV, base power = 100MVA.

## *Appendix-E*

**Table E1** The line data and load data for 30-node network

SN	RN	Length In km	Cond. Type*	Load kVA
1	2	0.2	1	100
2	3	0.2	1	100
3	4	0.43	2	100
4	5	0.6	2	300

1. Kultar Deep Singh and Smarajit Ghosh, “A New Efficient Method for Load-Flow Solution for Radial Distribution Networks”, *Przegląd Elektrotechniczny (Electrical Review)*, vol.12a’11, pp. 66-73, December 2011. (Impact Factor 0.24)
2. Kultar Deep Singh and Smarajit Ghosh, “Voltage stability index and Line loadability index for radial power distribution networks”, *International Review of Electrical Engineering*, Vol. 6, no. 7, pp-3111-3121, December 2011. (Impact Factor 1.364)

## *Biography*

**Kultar Deep Singh:** Born in Ludhiana, Punjab, India on 22<sup>nd</sup> February, 1978. He did B. Tech. (Elect. Engg.), M. Tech.(Power Engg.) from Punjab Technical University, Jalandhar Punjab, India, in 2001 and 2004 respectively. He is pursuing Ph. D. as regular research scholar in Department of Electrical and Instrumentation Engineering of Thapar University, Patiala, Punjab, India Under the supervision of Prof. Smarajit Ghosh.

His areas of interest are load-flow, line loadability, optimal conductor size selection, optimal capacitor placement etc. for electrical power distribution networks.

Contact email: [kultar22@yahoo.com](mailto:kultar22@yahoo.com)

**Smarajit Ghosh:** Born in Ghatal, West Bengal, India on 16 August, 1967. He did his B. Tech., M. Tech. in Electrical Machines and Power Systems from Calcutta University in 1994 and 1996 respectively. Finally, he did his Ph.D. from Indian Institute of Technology, Kharagpur, India in 2000.

His research areas include load–flow study, network reconfigurations, optimum capacitor allocation, application of soft computing in Electrical Power Distribution Systems, data-security. He has already served REC (Durgapur), BITS Pilani and Sikkaim Manipal University, as a lecturer, Assistant Professor and Professor respectively.

He has authored a number of books published by Printice Hall of India Private Limited and Pearson Education as a single auther.

Smarajit Ghosh is serving as a Professor in Thapar University Patiala, Department of Electrical and Instrumentation Engineering.
