ABSTRACT

This study attempts to study the functional parameters of pavements like roughness, rutting and texture which also includes various pavement distress like Cracking, ravelling etc. In addition, the study also focus on the importance of the Network survey vehicle and the how the NSV operates on the road at a high speed while analyzing the various parameters (mentioned above), saving the time and improving the accuracy of the data captured.

For this study, few National Highways were selected while undergoing internship at G-Eng Advisory Services Private Ltd. Different type of national highways like flexible pavement, mix roads(flexible and rigid pavements), Expressways, mountainous roads to analyze the working of NSV at different site conditions.

The data is presented in accordance of National Highway Authority of India (NHAI) i.e RIS templates which is uploaded on the RAMS site of NHAI which helps the authority to make a maintenance plan for the pavement using HDM-4. In addition, conclusion is also added in the form of summary length for roughness and rutting for better assessment of the present condition of the pavement.

INTRODUCTION

Roads make a crucial contribution to economic development and growth and bring important social benefits. They are of vital importance in order to make a nation grow and develop. In addition, providing access to employment, social, health and education services makes a road network crucial in fighting against poverty. Roads open up more areas and stimulate economic and social development. For those reasons, road infrastructure is the most important of all public assets.

Adequately maintaining road infrastructure is essential to preserve and enhance those benefits. But a backlog of outstanding maintenance has caused irreversible deterioration of the road network. If insufficient maintenance is carried out, roads can need replacing or major repairs after just a few years. That deterioration spread across a road system very quickly results in soaring costs and a major financial impact on the economy and citizens.

To preserve the assets by preventive maintenance and to balance the long-term need, Road Asset Management programmes or systems can be applied, to benefit different road stakeholders.

Management of the road asset involves the application of engineering, financial and management practices to optimise the level-of-service outcome in return for the most cost-effective financial input. Indeed, the main objective is simply to apply the right treatment at the right time to achieve the desired level of service, indicating that the road infrastructure is a financial asset for society and the economy.

Figure 1.3 LCMS Real Time Survey Display During Survey (Each section is of 10m length)

1.2.3. Laser Crack Measurement System (LCMS Module)

Integrated into the NSV is a Laser Profilometer consisting of 2 lasers. This inertial profiler is capable of measuring Surface Pavement Roughness (one laser in each wheel path)

The outputs of the lasers and accelerometers located in each wheel path (750 mm either side of the centreline of the vehicle) are sampled every 25 mm of longitudinal travel and are used to calculate the longitudinal profile of the road.

The profile is then passed through the Quarter Car model to calculate the International Roughness Index (IRI) lane roughness as per the methodologies specified in the Austroads Guide to Asset Management, Part 5B - Roughness.

Post survey, any spikes in the roughness outputs will be excluded that may arise from rumble strips, speed breakers, expansion joints, cattle grids, railway crossings, bridge abutments etc. Automated checks in the data processing software are already incorporated to exclude any contribution to roughness from data collected below the minimum survey speed which is typically set at 5-30 kmph (user definable).

* The above-mentioned Roughness Digital Laser Profile System fall under the specification defined in Circular no 11041/218/2007 - admin issued by NHAI for use of Laser Profilometer in NHAI Works and Circular No. RW / NH-33044/ 32/2019 issued by Surface & Roads Division of MINISTRY OF ROAD TRANSPORT & HIGHWAYS, GOVERNMENT OF INDIA Dated 13th November,2019

1.3.1.4 Rutting Data

Rutting refers to the coverage of ruts over a pavement, and is a pavement condition parameter that characterises the transverse profile of a road surface. A rut is defined as a longitudinal depression that forms in a wheel path of a road. Rutting may occur in one or both wheel paths of a lane.

Rut depth is the maximum vertical pavement displacement in the transverse profile, either across a wheel path (wheel path rut depth), or across a lane width (lane rut depth), measured from a reference datum taken at 90 degrees to the road edge.

Both traffic loading and environmental influences can cause or contribute to rutting. Traffic loading causes rutting when the passage of loaded wheels, particularly heavy trucks, results in a longitudinal depression in a road surface along a wheel path, due to deformation or abrasion or a combination of both.

When moisture causes deformation of a road pavement, subgrade or shoulder (e.g. heaving of the road shoulder or pavement edge), this can result in a longitudinal depression that is reported as rutting.

CHAPTER-2 CONDITION ASSESSMENT OF EXISTING PAVEMENT

2.1. General

Highway pavements are layered structures comprising of combination of materials to carry traffic load in given climate for a specified time interval. The pavement structure is designed in such a way that the transmitted stresses due to wheel load are sufficiently reduced, so that they will not exceed bearing capacity of the sub-grade. It should also be able to provide a surface of acceptable riding quality under all weather conditions with the highest possible degree of safety.

The performance of any highway pavement is measured by two indicators, namely Functional Performance and Structural Performance. The functional performance includes aspects such as riding quality, surface distress and skid resistance. Whilst recognizing these functional requirements, the pavement should also have adequate strength as a load bearing structure that is required to carry the traffic load under the prevailing environmental conditions (structural performance).

Table 2.1-1 Typical Distress types Associated with Performance

Performance Type	Performance Indicator
Functional	1. Riding Quality (Roughness and Rutting) 2. Surface Distress (Cracking, Bleeding, Potholes, Raveling etc.)

Information about pavement condition and performance is critical to the decision-making process for successful management of highway pavements. The objective of condition assessment of the pavement is to collect accurate and timely data, analyze the level of deterioration, identify maintenance and reconstruction needs, and determine maintenance costs both routine as well as periodic (major maintenance).

In this context, series of surveys was undertaken using a combination of state-of-the-art technology-driven fully automated and semi-automated processes with high-speed data collection in field. The methodology and data collection involved in the above-mentioned surveys are elaborated in the Chapter 2. After collecting the pavement condition data from these tests, the data is analyzed to evaluate the pavement performance or condition which included the following aspects:

- a. Analysis of Riding Quality in terms of Roughness and Rutting parameters
- b. Analysis of Surface Distresses

1.1 Analysis of Network Survey Vehicle (NSV) Data

The analysis of various performance parameter data as collected during NSV survey is presented in this section.

2.2. Roughness Analysis

Roughness is one of the important parameters for determining the functional characteristics of pavements. According to American Society for Testing and Materials (ASTM), roughness is defined as “the deviations of a pavement surface from a true planar surface with characteristic dimensions that affect vehicle dynamics, ride quality, dynamic loads, and drainage, for example, longitudinal profile, transverse profile and cross slope”.

The International Roughness Index (IRI), Bump Integrator Roughness (BI) is used to define the characteristics of a longitudinal road profile and constitutes a standardized roughness measurement. IRI & BI is measured in meters per kilometer (m/km) & millimeters per kilometer (mm/km) respectively.

The roughness of road surfaces is measured using different equipment/techniques such as rod and level survey, dip stick profiler, profilographs, response type road roughness meters and profiling devices.

The International Roughness Index (IRI) is a scale for roughness based on the response of a generic motor vehicle (called the Golden car or the quarter-car model) to roughness of the road surface. Its true value is determined by obtaining a suitably accurate measurement of the profile of the road, processing it through an algorithm that simulates the way a reference vehicle would respond to the roughness inputs, and accumulating the suspension travel.

IRI is the accumulation of motion between the sprung mass and unsprung mass normalized by length of the road file.

The underlying IRI model is a series of differential equations which relate the motions of a simulated quarter-car to the road profile.

Figure 2.1 IRI Model Simulating motions of Quarter-car to the road Profile 11

Characteristic's of IRI

- j. Reproducible
- k. Portable
- l. Stable with time

Defined as property of the true profile and therefore can be measured by any valid profiler

IRI summarizes the impact vehicle response, and is therefore appropriate when a roughness measure is desired that relates to

- m. Overall vehicle operating costs
- n. Ride quality
- o. Dynamic wheel loads
- p. Surface condition

Correlation between Bump Integrator Roughness (BI)/ Unevenness Index (UI) and International Roughness Index (IRI) (As per IRC:SP:16-2019)

The accepted world standard for Roughness is the International Roughness Index (IRI). The IRI was an outcome of the International Road Roughness Experiment conducted in Brazil (Sayers et al., 1986a) and is reproducible, portable and stable with time. The equipment is included with software to calculate and print various profile statistics including the IRI as well as the individual point elevation and local surface curvatures. For correlation with BI/UI values, the following relation mentioned in **Annexure-1 Page No. 12 of IRC:SP:16-2019 Guidelines for the Surface Evenness of Highway Pavements as:**

$$BI=630(IRI)^{1.12}$$

Where,

BI= Bump Integrator Roughness or Unevenness Index in mm/km

IRI= International Roughness Index

2.2.1.1. Recommended Standard for Roughness Values

The maximum permissible value of surface roughness for different surface is given in table below as per **IRC-SP: 16-2019**

Table 2.2.: Maximum Permissible Roughness Values for different pavement surfaces

S.No.	Type of Surface	Condition of Road Surfaces					
		Good		Fair		Poor	
		R1	IRI	R1	IRI	R1	IRI
1.	Bituminous (BC,SMA,SDBC)	<1800	<2.55	1800-2400	2.55-3.30	>2400	>3.30
2.	Cemented	<2000	<2.81	2000-2400	2.81-3.30	>2400	>3.30

Note: In case of four lane divided and above corridors, roughness measurements shall be carried out using Class 1 Equipment, For Other Corridors, the roughness measurements shall be carried out using Class1/Class2 or Class 3 equipment depending upon survey speed/geometric suitability.

Newly constructed surface are expected to give roughness values corresponding to GOOD category while the value under AVERAGE and POOR category indicate level-of-service and intervention level for maintenance.

2.3. Rutting Analysis

Rutting is one of the important factors which determine the functional performance of pavement.

Rutting is characterized by permanent deformation of the pavement in wheel path due to heavy load vehicles. It is one of the main modes of failure in asphalt mixes.

Length wise summary of Rut depth condition details for both the directions is given in table below:

Table 4: Standard Rutting Depth Range and Severity

Rut Depth Range (mm)	Severity
Less than 4mm	No Rutting
Between 4mm & 10mm	Low
